If the Amazon EC2 action that you are testing creates or modifies a resource, you should make the request using the `DryRun` parameter (or run the AWS CLI command with the `--dry-run` option). In this case, the call completes the authorization check, but does not complete the operation. For example, you can check whether the user can terminate a particular instance without actually terminating it. If the test user has the required permissions, the request returns `DryRunOperation`; otherwise, it returns `UnauthorizedOperation`.

If the policy doesn't grant the user the permissions that you expected, or is overly permissive, you can adjust the policy as needed and retest until you get the desired results.

> **Important**
>
> It can take several minutes for policy changes to propagate before they take effect. Therefore, we recommend that you allow five minutes to pass before you test your policy updates.

If an authorization check fails, the request returns an encoded message with diagnostic information. You can decode the message using the `DecodeAuthorizationMessage` action.

For more information, see DecodeAuthorizationMessage in the *AWS Security Token Service API Reference*, and decode-authorization-message.

Example policies to control access the Amazon EC2 API

You can use IAM policies to grant users the permissions required to work with Amazon EC2. For step-by-step directions, see Creating IAM policies in the *IAM User Guide*.

The following examples show policy statements that you could use to grant users permissions to use Amazon EC2. These policies are designed for requests that are made using the AWS CLI or an AWS SDK. In the following examples, replace each *`user input placeholder`* with your own information.

Examples

- Example: Read-only access
- Example: Restrict access to a specific Region
- Work with instances
- Launch instances (RunInstances)
- Work with Spot Instances
- Example: Work with Reserved Instances
- Example: Tag resources
- Example: Work with IAM roles
- Example: Work with route tables
- Example: Allow a specific instance to view resources in other AWS services
- Example: Work with launch templates
- Work with instance metadata
- Work with Amazon EBS volumes and snapshots

For example policies for working in the Amazon EC2 console, see Example policies to control access to the Amazon EC2 console.

Example: Read-only access

The following policy grants users permissions to use all Amazon EC2 API actions whose names begin with `Describe`. The `Resource` element uses a wildcard to indicate that users can specify all resources with these API actions. The * wildcard is also necessary in cases where the API action does

not support resource-level permissions. For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

Users don't have permission to perform any actions on the resources (unless another statement grants them permission to do so) because they're denied permission to use API actions by default.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:Describe*",
      "Resource": "*"
    }
   ]
}
```

Example: Restrict access to a specific Region

The following policy denies users permission to use all Amazon EC2 API actions unless the Region is Europe (Frankfurt). It uses the global condition key `aws:RequestedRegion`, which is supported by all Amazon EC2 API actions.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
       {
      "Effect": "Deny",
      "Action": "ec2:*",
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:RequestedRegion": "eu-central-1"
        }
      }
    }
```

```
  ]
}
```

Alternatively, you can use the condition key `ec2:Region`, which is specific to Amazon EC2 and is supported by all Amazon EC2 API actions.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
       {
      "Effect": "Deny",
      "Action": "ec2:*",
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "ec2:Region": "eu-central-1"
        }
      }
    }
  ]
}
```

Work with instances

Examples

- Example: Describe, launch, stop, start, and terminate all instances
- Example: Describe all instances, and stop, start, and terminate only particular instances

Example: Describe, launch, stop, start, and terminate all instances

The following policy grants users permissions to use the API actions specified in the `Action` element. The `Resource` element uses a * wildcard to indicate that users can specify all resources with these API actions. The * wildcard is also necessary in cases where the API action does not support resource-level permissions. For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

The users don't have permission to use any other API actions (unless another statement grants them permission to do so) because users are denied permission to use API actions by default.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeInstances",
        "ec2:DescribeImages",
        "ec2:DescribeKeyPairs",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeAvailabilityZones",
        "ec2:RunInstances",
        "ec2:TerminateInstances",
        "ec2:StopInstances",
        "ec2:StartInstances"
      ],
      "Resource": "*"
    }
   ]
}
```

Example: Describe all instances, and stop, start, and terminate only particular instances

The following policy allows users to describe all instances, to start and stop only instances i-1234567890abcdef0 and i-0598c7d356eba48d7, and to terminate only instances in the `eusc-de-east-1` Region, with the resource tag "`purpose=test`".

The first statement uses a * wildcard for the `Resource` element to indicate that users can specify all resources with the action; in this case, they can list all instances. The * wildcard is also necessary in cases where the API action does not support resource-level permissions (in this case, `ec2:DescribeInstances`). For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

The second statement uses resource-level permissions for the `StopInstances` and `StartInstances` actions. The specific instances are indicated by their ARNs in the `Resource` element.

The third statement allows users to terminate all instances in the `eusc-de-east-1` Region that belong to the specified AWS account, but only where the instance has the tag `"purpose=test"`. The `Condition` element qualifies when the policy statement is in effect.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
      "Action": "ec2:DescribeInstances",
      "Resource": "*"
   },
   {
      "Effect": "Allow",
      "Action": [
        "ec2:StopInstances",
        "ec2:StartInstances"
      ],
      "Resource": [
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/
i-1234567890abcdef0",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/
i-0598c7d356eba48d7"
      ]
    },
    {
      "Effect": "Allow",
      "Action": "ec2:TerminateInstances",
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*",
      "Condition": {
         "StringEquals": {
            "aws:ResourceTag/purpose": "test"
         }
      }
   }
```

```
    ]
}
```

Launch instances (RunInstances)

The RunInstances API action launches one or more On-Demand Instances or one or more Spot Instances. `RunInstances` requires an AMI and creates an instance. Users can specify a key pair and security group in the request. Launching into a VPC requires a subnet, and creates a network interface. Launching from an Amazon EBS-backed AMI creates a volume. Therefore, the user must have permissions to use these Amazon EC2 resources. You can create a policy statement that requires users to specify an optional parameter on `RunInstances`, or restricts users to particular values for a parameter.

For more information about the resource-level permissions that are required to launch an instance, see Actions, resources, and condition keys for Amazon EC2.

By default, users don't have permissions to describe, start, stop, or terminate the resulting instances. One way to grant the users permission to manage the resulting instances is to create a specific tag for each instance, and then create a statement that enables them to manage instances with that tag. For more information, see Work with instances.

Resources

- AMIs
- Instance types
- Subnets
- EBS volumes

- Tags in a launch template
- Elastic GPUs
- Launch templates

AMIs

The following policy allows users to launch instances using only the specified AMIs, `ami-9e1670f7` and `ami-45cf5c3c`. The users can't launch an instance using other AMIs (unless another statement grants the users permission to do so).

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
   {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws-eusc:ec2:eusc-de-east-1::image/ami-9e1670f7",
        "arn:aws-eusc:ec2:eusc-de-east-1::image/ami-45cf5c3c",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:volume/*",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:key-pair/*",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group/*",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/*",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-interface/*"
      ]
    }
   ]
}
```

Alternatively, the following policy allows users to launch instances from all AMIs owned by Amazon, or certain trusted and verified partners. The `Condition` element of the first statement tests whether `ec2:Owner` is `amazon`. The users can't launch an instance using other AMIs (unless another statement grants the users permission to do so).

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
         {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
         "arn:aws-eusc:ec2:eusc-de-east-1::image/ami-*"
      ],
      "Condition": {
         "StringEquals": {
```

```
            "ec2:Owner": "amazon"
         }
      }
   },
   {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:volume/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-interface/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:key-pair/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group/*"
         ]
      }
   ]
}
```

Instance types

The following policy allows users to launch instances using only the `t2.micro` or `t2.small` instance type, which you might do to control costs. The users can't launch larger instances because the `Condition` element of the first statement tests whether `ec2:InstanceType` is either `t2.micro` or `t2.small`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
        {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*"
      ],
      "Condition": {
         "StringEquals": {
            "ec2:InstanceType": ["t2.micro", "t2.small"]
         }
```

```
      }
   },
   {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
         "arn:aws-eusc:ec2:eusc-de-east-1::image/ami-*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-interface/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:volume/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:key-pair/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group/*"
         ]
      }
   ]
}
```

Alternatively, you can create a policy that denies users permissions to launch any instances except `t2.micro` and `t2.small` instance types.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
        {
      "Effect": "Deny",
      "Action": "ec2:RunInstances",
      "Resource": [
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*"
      ],
      "Condition": {
         "StringNotEquals": {
            "ec2:InstanceType": ["t2.micro", "t2.small"]
         }
      }
   },
   {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
```

```
            "arn:aws-eusc:ec2:eusc-de-east-1::image/ami-*",
            "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-interface/*",
            "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*",
            "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/*",
            "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:volume/*",
            "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:key-pair/*",
            "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group/*"
            ]
      }
   ]
}
```

Subnets

The following policy allows users to launch instances using only the specified subnet, `subnet-12345678`. The group can't launch instances into any another subnet (unless another statement grants the users permission to do so).

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/subnet-12345678",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-interface/*",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:volume/*",
        "arn:aws-eusc:ec2:eusc-de-east-1::image/ami-*",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:key-pair/*",
        "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group/*"
      ]
    }
   ]
}
```

Alternatively, you could create a policy that denies users permissions to launch an instance into any other subnet. The statement does this by denying permission to create a network interface, except where subnet `subnet-12345678` is specified. This denial overrides any other policies that are created to allow launching instances into other subnets.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
         {
      "Effect": "Deny",
      "Action": "ec2:RunInstances",
      "Resource": [
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-interface/*"
      ],
      "Condition": {
         "ArnNotEquals": {
            "ec2:Subnet": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/
subnet-12345678"
         }
      }
   },
   {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
         "arn:aws-eusc:ec2:eusc-de-east-1::image/ami-*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-interface/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:volume/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:key-pair/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group/*"
         ]
      }
   ]
}
```

EBS volumes

The following policy allows users to launch instances only if the EBS volumes for the instance are encrypted. The user must launch an instance from an AMI that was created with encrypted snapshots, to ensure that the root volume is encrypted. Any additional volume that the user attaches to the instance during launch must also be encrypted.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
                {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws-eusc:ec2:*:*:volume/*"
            ],
            "Condition": {
                "Bool": {
                    "ec2:Encrypted": "true"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws-eusc:ec2:*::image/ami-*",
                "arn:aws-eusc:ec2:*:*:network-interface/*",
                "arn:aws-eusc:ec2:*:*:instance/*",
                "arn:aws-eusc:ec2:*:*:subnet/*",
                "arn:aws-eusc:ec2:*:*:key-pair/*",
                "arn:aws-eusc:ec2:*:*:security-group/*"
            ]
        }
    ]
}
```

Tags

Tag instances on creation

The following policy allows users to launch instances and tag the instances during creation. For resource-creating actions that apply tags, users must have permissions to use the `CreateTags` action. The second statement uses the `ec2:CreateAction` condition key to allow users to create tags only in the context of `RunInstances`, and only for instances. Users cannot tag existing resources, and users cannot tag volumes using the `RunInstances` request.

For more information, see Grant permission to tag Amazon EC2 resources during creation.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateTags"
      ],
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*",
      "Condition": {
         "StringEquals": {
             "ec2:CreateAction" : "RunInstances"
          }
       }
    }
  ]
}
```

Tag instances and volumes on creation with specific tags

The following policy includes the `aws:RequestTag` condition key that requires users to tag any instances and volumes that are created by `RunInstances` with the tags `environment=production` and `purpose=webserver`. If users don't pass these specific tags, or if they don't specify tags at all, the request fails.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
   {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
      ],
      "Resource": [
         "arn:aws-eusc:ec2:eusc-de-east-1::image/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-interface/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:key-pair/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
      ],
      "Resource": [
          "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:volume/*",
          "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*"
      ],
      "Condition": {
         "StringEquals": {
            "aws:RequestTag/environment": "production" ,
            "aws:RequestTag/purpose": "webserver"
          }
       }
    },
    {
      "Effect": "Allow",
      "Action": [
```

```
            "ec2:CreateTags"
         ],
         "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:*/*",
         "Condition": {
            "StringEquals": {
                "ec2:CreateAction" : "RunInstances"
             }
          }
      }
   ]
}
```

Tag instances and volumes on creation with at least one specific tag

The following policy uses the `ForAnyValue` modifier on the `aws:TagKeys` condition to indicate that at least one tag must be specified in the request, and it must contain the key `environment` or `webserver`. The tag must be applied to both instances and volumes. Any tag values can be specified in the request.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
   {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
      ],
      "Resource": [
         "arn:aws-eusc:ec2:eusc-de-east-1::image/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-interface/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group/*",
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:key-pair/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
          "ec2:RunInstances"
```

```
      ],
      "Resource": [
          "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:volume/*",
          "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*"
      ],
      "Condition": {
          "ForAnyValue:StringEquals": {
              "aws:TagKeys": ["environment","webserver"]
          }
       }
    },
    {
      "Effect": "Allow",
      "Action": [
          "ec2:CreateTags"
      ],
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:*/*",
      "Condition": {
          "StringEquals": {
              "ec2:CreateAction" : "RunInstances"
          }
       }
    }
  ]
}
```

If instances are tagged on creation, they must be tagged with a specific tag

In the following policy, users do not have to specify tags in the request, but if they do, the tag must be `purpose=test`. No other tags are allowed. Users can apply the tags to any taggable resource in the `RunInstances` request.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
```

```
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateTags"
      ],
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:*/*",
      "Condition": {
         "StringEquals": {
             "aws:RequestTag/purpose": "test",
             "ec2:CreateAction" : "RunInstances"
          },
          "ForAllValues:StringEquals": {
              "aws:TagKeys": "purpose"
          }
       }
    }
  ]
}
```

To disallow anyone called tag on create for RunInstances

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws-eusc:ec2:eusc-de-east-1::image/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:subnet/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:network-interface/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:security-group/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:key-pair/*",
```

```
                "arn:aws-eusc:ec2:eusc-de-east-1:*:volume/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:instance/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:spot-instances-request/*"
            ]
        },
        {
            "Effect": "Deny",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```

Only allow specific tags for spot-instances-request. Surprise inconsistency number 2 comes into play here. Under normal circumstances, specifying no tags will result in Unauthenticated. In the case of spot-instances-request, this policy will not be evaluated if there are no spot-instances-request tags, so a non-tag Spot on Run request will succeed.

Tags in a launch template

In the following example, users can launch instances, but only if they use a specific launch template (`lt-09477bcd97b0d310e`). The `ec2:IsLaunchTemplateResource` condition key prevents users from overriding any of the resources specified in the launch template. The second part of the statement allows users to tag instances on creation—this part of the statement is necessary if tags are specified for the instance in the launch template.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
   {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*",
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws-eusc:ec2:eusc-de-
east-1:111122223333:launch-template/lt-09477bcd97b0d310e"
          },
          "Bool": {
```

```
            "ec2:IsLaunchTemplateResource": "true"
          }
        }
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateTags"
      ],
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*",
      "Condition": {
         "StringEquals": {
            "ec2:CreateAction" : "RunInstances"
         }
        }
    }
  ]
}
```

Elastic GPUs

In the following policy, users can launch an instance and specify an elastic GPU to attach to the instance. Users can launch instances in any Region, but they can only attach an elastic GPU during a launch in the `us-east-2` Region.

The `ec2:ElasticGpuType` condition key ensures that instances use either the `eg1.medium` or `eg1.large` elastic GPU type.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
            {
           "Effect": "Allow",
           "Action": [
               "ec2:RunInstances"
           ],
           "Resource": [
               "arn:aws-eusc:ec2:*:111122223333:elastic-gpu/*"
           ],
```

```
            "Condition": {
                "StringEquals": {
                    "ec2:Region": "us-east-2",
                    "ec2:ElasticGpuType": [
                        "eg1.medium",
                        "eg1.large"
                    ]
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws-eusc:ec2:*::image/ami-*",
                "arn:aws-eusc:ec2:*:111122223333:network-interface/*",
                "arn:aws-eusc:ec2:*:111122223333:instance/*",
                "arn:aws-eusc:ec2:*:111122223333:subnet/*",
                "arn:aws-eusc:ec2:*:111122223333:volume/*",
                "arn:aws-eusc:ec2:*:111122223333:key-pair/*",
                "arn:aws-eusc:ec2:*:111122223333:security-group/*"
            ]
        }
    ]
}
```

Launch templates

In the following example, users can launch instances, but only if they use a specific launch template (`lt-09477bcd97b0d310e`). Users can override any parameters in the launch template by specifying the parameters in the `RunInstances` action.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
        {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*",
```

```
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws-eusc:ec2:eusc-de-
east-1:111122223333:launch-template/lt-09477bcd97b0d310e"
          }
       }
    }
  ]
}
```

In this example, users can launch instances only if they use a launch template. The policy uses the `ec2:IsLaunchTemplateResource` condition key to prevent users from overriding any pre-existing ARNs in the launch template.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
         {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*",
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws-eusc:ec2:eusc-de-
east-1:111122223333:launch-template/*"
          },
          "Bool": {
             "ec2:IsLaunchTemplateResource": "true"
          }
       }
    }
  ]
}
```

The following example policy allows user to launch instances, but only if they use a launch template. Users cannot override the subnet and network interface parameters in the request; these parameters can only be specified in the launch template. The first part of the statement uses the

NotResource element to allow all other resources except subnets and network interfaces. The second part of the statement allows the subnet and network interface resources, but only if they are sourced from the launch template.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
        {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "NotResource": ["arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/*",
                      "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-
interface/*" ],
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws-eusc:ec2:eusc-de-
east-1:111122223333:launch-template/*"
          }
       }
    },
   {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": ["arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/*",
                   "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-
interface/*" ],
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws-eusc:ec2:eusc-de-
east-1:111122223333:launch-template/*"
          },
          "Bool": {
             "ec2:IsLaunchTemplateResource": "true"
          }
       }
    }
  ]
}
```

The following example allows users to launch instances only if they use a launch template, and only if the launch template has the tag `Purpose=Webservers`. Users cannot override any of the launch template parameters in the `RunInstances` action.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
        {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "NotResource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:launch-
template/*",
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws-eusc:ec2:eusc-de-
east-1:111122223333:launch-template/*"
          },
         "Bool": {
             "ec2:IsLaunchTemplateResource": "true"
          }
       }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:launch-template/
*",
      "Condition": {
       "StringEquals": {
           "aws:ResourceTag/Purpose": "Webservers"
        }
       }
     }
  ]
}
```

Work with Spot Instances

You can use the RunInstances action to create Spot Instance requests, and tag the Spot Instance requests on create. The resource to specify for RunInstances is `spot-instances-request`.

The `spot-instances-request` resource is evaluated in the IAM policy as follows:

- If you don't tag a Spot Instance request on create, Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement.
- If you tag a Spot Instance request on create, Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement.

Therefore, for the `spot-instances-request` resource, the following rules apply to the IAM policy:

- If you use RunInstances to create a Spot Instance request and you don't intend to tag the Spot Instance request on create, you don’t need to explicitly allow the `spot-instances-request` resource; the call will succeed.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must include the `spot-instances-request` resource in the RunInstances allow statement, otherwise the call will fail.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must specify the `spot-instances-request` resource or * wildcard in the CreateTags allow statement, otherwise the call will fail.

You can request Spot Instances using RunInstances or RequestSpotInstances. The following example IAM policies apply only when requesting Spot Instances using RunInstances.

Example: Request Spot Instances using RunInstances

The following policy allows users to request Spot Instances by using the RunInstances action. The `spot-instances-request` resource, which is created by RunInstances, requests Spot Instances.

> **Note**
>
> To use RunInstances to create Spot Instance requests, you can omit `spot-instances-request` from the `Resource` list if you do not intend to tag the Spot Instance requests

on create. This is because Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement if the Spot Instance request is not tagged on create.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws-eusc:ec2:eusc-de-east-1::image/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:subnet/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:network-interface/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:security-group/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:key-pair/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:volume/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:instance/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:spot-instances-request/*"
            ]
        }
    ]
}
```

Warning

NOT SUPPORTED – Example: Deny users permission to request Spot Instances using RunInstances

The following policy is not supported for the `spot-instances-request` resource.

The following policy is meant to give users the permission to launch On-Demand Instances, but deny users the permission to request Spot Instances. The `spot-instances-request` resource, which is created by RunInstances, is the resource that requests Spot Instances. The second statement is meant to deny the RunInstances action for the `spot-`

`instances-request` resource. However, this condition is not supported because Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement if the Spot Instance request is not tagged on create.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws-eusc:ec2:eusc-de-east-1::image/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:subnet/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:network-interface/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:security-group/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:key-pair/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:volume/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:instance/*"
            ]
        },
        {
            "Sid": "DenySpotInstancesRequestsNOTSUPPORTEDDONOTUSE",
            "Effect": "Deny",
            "Action": "ec2:RunInstances",
            "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:*:spot-instances-
request/*"
        }
    ]
}
```

Example: Tag Spot Instance requests on create

The following policy allows users to tag all resources that are created during instance launch. The first statement allows RunInstances to create the listed resources. The `spot-instances-request` resource, which is created by RunInstances, is the resource that requests Spot Instances.

The second statement provides a * wildcard to allow all resources to be tagged when they are created at instance launch.

> **Note**
>
> If you tag a Spot Instance request on create, Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement. Therefore, you must explicitly allow the `spot-instances-request` resource for the RunInstances action, otherwise the call will fail.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws-eusc:ec2:eusc-de-east-1::image/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:subnet/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:network-interface/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:security-group/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:key-pair/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:volume/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:instance/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:spot-instances-request/*"
            ]
        },
        {
            "Sid": "TagResources",
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```

Example: Deny tag on create for Spot Instance requests

The following policy denies users the permission to tag the resources that are created during instance launch.

The first statement allows RunInstances to create the listed resources. The `spot-instances-request` resource, which is created by RunInstances, is the resource that requests Spot Instances. The second statement provides a * wildcard to deny all resources being tagged when they are created at instance launch. If `spot-instances-request` or any other resource is tagged on create, the RunInstances call will fail.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",

            "Effect": "Deny",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```

Warning

NOT SUPPORTED – Example: Allow creating a Spot Instance request only if it is assigned a specific tag

The following policy is not supported for the `spot-instances-request` resource.
The following policy is meant to grant RunInstances the permission to create a Spot Instance request only if the request is tagged with a specific tag.
The first statement allows RunInstances to create the listed resources.
The second statement is meant to grant users the permission to create a Spot Instance request only if the request has the tag `environment=production`. If this condition is applied to other resources created by RunInstances, specifying no tags results in an `Unauthenticated` error. However, if no tags are specified for the Spot Instance request, Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement, which results in non-tagged Spot Instance requests being created by RunInstances.
Note that specifying another tag other than `environment=production` results in an `Unauthenticated` error, because if a user tags a Spot Instance request, Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws-eusc:ec2:eusc-de-east-1::image/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:subnet/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:network-interface/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:security-group/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:key-pair/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:volume/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:instance/*"
            ]
```

```
        },
        {
            "Sid":
 "RequestSpotInstancesOnlyIfTagIsEnvironmentProductionNOTSUPPORTEDDONOTUSE",
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:*:spot-instances-
request/*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/environment": "production"
                }
            }
        },
        {
            "Sid": "TagResources",
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }

    ]
}
```

Example: Deny creating a Spot Instance request if it is assigned a specific tag

The following policy denies RunInstances the permission to create a Spot Instance request if the request is tagged with `environment=production`.

The first statement allows RunInstances to create the listed resources.

The second statement denies users the permission to create a Spot Instance request if the request has the tag `environment=production`. Specifying `environment=production` as a tag results in an `Unauthenticated` error. Specifying other tags or specifying no tags will result in the creation of a Spot Instance request.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
```

```
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws-eusc:ec2:eusc-de-east-1::image/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:subnet/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:network-interface/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:security-group/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:key-pair/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:volume/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:instance/*",
                "arn:aws-eusc:ec2:eusc-de-east-1:*:spot-instances-request/*"
            ]
        },
        {
            "Sid": "DenySpotInstancesRequests",
            "Effect": "Deny",
            "Action": "ec2:RunInstances",
            "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:*:spot-instances-
request/*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/environment": "production"
                }
            }
        },
        {
            "Sid": "TagResources",
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```

Example: Work with Reserved Instances

The following policy gives users permission to view, modify, and purchase Reserved Instances in your account.

It is not possible to set resource-level permissions for individual Reserved Instances. This policy means that users have access to all the Reserved Instances in the account.

The `Resource` element uses a * wildcard to indicate that users can specify all resources with the action; in this case, they can list and modify all Reserved Instances in the account. They can also purchase Reserved Instances using the account credentials. The * wildcard is also necessary in cases where the API action does not support resource-level permissions.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeReservedInstances",
        "ec2:ModifyReservedInstances",
        "ec2:PurchaseReservedInstancesOffering",
        "ec2:DescribeAvailabilityZones",
        "ec2:DescribeReservedInstancesOfferings"
      ],
      "Resource": "*"
    }
   ]
}
```

To allow users to view and modify the Reserved Instances in your account, but not purchase new Reserved Instances.

JSON

```
{
  "Version":"2012-10-17",
   "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeReservedInstances",
        "ec2:ModifyReservedInstances",
```

```
        "ec2:DescribeAvailabilityZones"
      ],
      "Resource": "*"
    }
  ]
}
```

Example: Tag resources

The following policy allows users to use the `CreateTags` action to apply tags to an instance only if the tag contains the key`environment` and the value `production`. No other tags are allowed and the user cannot tag any other resource types.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
              {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
            ],
            "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/
*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/environment": "production"
                }
            }
        }
    ]
}
```

The following policy allows users to tag any taggable resource that already has a tag with a key of `owner` and a value of the username. In addition, users must specify a tag with a key of `anycompany:environment-type` and a value of either `test` or `prod` in the request. Users can specify additional tags in the request.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
                {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
            ],
            "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:*/*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/anycompany:environment-type":
 ["test","prod"],
                    "aws:ResourceTag/owner": "${aws:username}"
                }
            }
        }
    ]
}
```

You can create an IAM policy that allows users to delete specific tags for a resource. For example, the following policy allows users to delete tags for a volume if the tag keys specified in the request are `environment` or `cost-center`. Any value can be specified for the tag but the tag key must match either of the specified keys.

> **Note**
>
> If you delete a resource, all tags associated with the resource are also deleted. Users do not need permissions to use the `ec2:DeleteTags` action to delete a resource that has tags; they only need permissions to perform the deleting action.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
```

```
       {
      "Effect": "Allow",
      "Action": "ec2:DeleteTags",
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:volume/*",
      "Condition": {
        "ForAllValues:StringEquals": {
          "aws:TagKeys": ["environment","cost-center"]
        }
      }
    }
  ]
}
```

This policy allows users to delete only the `environment=prod` tag on any resource, and only if the resource is already tagged with a key of `owner` and a value of the username. Users can't delete any other tags for a resource.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
      {
      "Effect": "Allow",
      "Action": [
        "ec2:DeleteTags"
      ],
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:*/*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/environment": "prod",
          "aws:ResourceTag/owner": "${aws:username}"
        },
        "ForAllValues:StringEquals": {
          "aws:TagKeys": ["environment"]
        }
      }
    }
  ]
}
```

Example: Work with IAM roles

The following policy allows users to attach, replace, and detach an IAM role to instances that have the tag `department=test`. Replacing or detaching an IAM role requires an association ID, therefore the policy also grants users permission to use the `ec2:DescribeIamInstanceProfileAssociations` action.

Users must have permission to use the `iam:PassRole` action to pass the role to the instance.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AssociateIamInstanceProfile",
        "ec2:ReplaceIamInstanceProfileAssociation",
        "ec2:DisassociateIamInstanceProfile"
      ],
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/department":"test"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:DescribeIamInstanceProfileAssociations",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws-eusc:iam::111122223333:role/DevTeam*"
    }
  ]
}
```

The following policy allows users to attach or replace an IAM role for any instance. Users can only attach or replace IAM roles with names that begin with `TestRole-`. For the `iam:PassRole` action, ensure that you specify the name of the IAM role and not the instance profile (if the names are different). For more information, see Instance profiles.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:AssociateIamInstanceProfile",
                "ec2:ReplaceIamInstanceProfileAssociation"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "ec2:DescribeIamInstanceProfileAssociations",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws-eusc:iam::111122223333:role/TestRole-*"
        }
    ]
}
```

Example: Work with route tables

The following policy allows users to add, remove, and replace routes for route tables that are associated with VPC `vpc-ec43eb89` only. To specify a VPC for the `ec2:Vpc` condition key, you must specify the full ARN of the VPC.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
              {
            "Effect": "Allow",
            "Action": [
                "ec2:DeleteRoute",
                "ec2:CreateRoute",
                "ec2:ReplaceRoute"
            ],
            "Resource": [
                "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:route-table/*"
            ],
            "Condition": {
                "StringEquals": {
                    "ec2:Vpc": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:vpc/
vpc-ec43eb89"
                }
            }
        }
    ]
}
```

Example: Allow a specific instance to view resources in other AWS services

The following is an example of a policy that you might attach to an IAM role. The policy allows an instance to view resources in various AWS services. It uses the `ec2:SourceInstanceARN` global condition key to specify that the instance from which the request is made must be instance `i-093452212644b0dd6`. If the same IAM role is associated with another instance, the other instance cannot perform any of these actions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
              {
            "Effect": "Allow",
```

```
            "Action": [
                "ec2:DescribeVolumes",
                "s3:ListAllMyBuckets",
                "dynamodb:ListTables",
                "rds:DescribeDBInstances"
            ],
            "Resource": [
                "*"
            ],
            "Condition": {
                "ArnEquals": {
                    "ec2:SourceInstanceARN": "arn:aws-eusc:ec2:eusc-de-
east-1:111122223333:instance/i-093452212644b0dd6"
                }
            }
        }
    ]
}
```

Example: Work with launch templates

The following policy allows users to create a launch template version and modify a launch template, but only for a specific launch template (`lt-09477bcd97b0d3abc`). Users cannot work with other launch templates.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
   {
      "Action": [
        "ec2:CreateLaunchTemplateVersion",
        "ec2:ModifyLaunchTemplate"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:launch-template/
lt-09477bcd97b0d3abc"
    }
  ]
}
```

The following policy allows users to delete any launch template and launch template version, provided that the launch template has the tag `Purpose=Testing`.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
       {
      "Action": [
        "ec2:DeleteLaunchTemplate",
        "ec2:DeleteLaunchTemplateVersions"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:launch-template/
*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Purpose": "Testing"
        }
      }
    }
  ]
}
```

Work with instance metadata

The following policies ensure that users can only retrieve instance metadata using Instance Metadata Service Version 2 (IMDSv2). You can combine the following four policies into one policy with four statements. When combined as one policy, you can use the policy as a service control policy (SCP). It can work equally well as a *deny* policy that you apply to an existing IAM policy (taking away and limiting existing permission), or as an SCP that is applied globally across an account, an organizational unit (OU), or an entire organization.

> **Note**
>
> The following RunInstances metadata options policies must be used in conjunction with a policy that gives the principal permissions to launch an instance with RunInstances. If the principal does not also have RunInstances permissions, it will not be able to launch

an instance. For more information, see the policies in Work with instances and Launch instances (RunInstances).

Important

If you use Auto Scaling groups and you need to require the use of IMDSv2 on all new instances, your Auto Scaling groups must use *launch templates*.
When an Auto Scaling group uses a launch template, the `ec2:RunInstances` permissions of the IAM principal are checked when a new Auto Scaling group is created. They are also checked when an existing Auto Scaling group is updated to use a new launch template or a new version of a launch template.
Restrictions on the use of IMDSv1 on IAM principals for `RunInstances` are only checked when an Auto Scaling group that is using a launch template, is created or updated. For an Auto Scaling group that is configured to use the `Latest` or `Default` launch template, the permissions are not checked when a new version of the launch template is created. For permissions to be checked, you must configure the Auto Scaling group to use a *specific version* of the launch template.

To enforce the use of IMDSv2 on instances launched by Auto Scaling groups, the following additional steps are required:

1. Disable the use of launch configurations for all accounts in your organization by using either service control policies (SCPs) or IAM permissions boundaries for new principals that are created. For existing IAM principals with Auto Scaling group permissions, update their associated policies with this condition key. To disable the use of launch configurations, create or modify the relevant SCP, permissions boundary, or IAM policy with the `"autoscaling:LaunchConfigurationName"` condition key with the value specified as `null`.
2. For new launch templates, configure the instance metadata options in the launch template. For existing launch templates, create a new version of the launch template and configure the instance metadata options in the new version.
3. In the policy that gives any principal the permission to use a launch template, restrict association of `$latest` and `$default` by specifying `"autoscaling:LaunchTemplateVersionSpecified": "true"`. By restricting the use to a specific version of a launch template, you can ensure that new instances will be launched using the version in which the instance metadata options are configured. For

more information, see LaunchTemplateSpecification in the *Amazon EC2 Auto Scaling API Reference*, specifically the `Version` parameter.

4. For an Auto Scaling group that uses a launch configuration, replace the launch configuration with a launch template. For more information, see Migrate your Auto Scaling groups to launch templates in the *Amazon EC2 Auto Scaling User Guide*.
5. For an Auto Scaling group that uses a launch template, make sure that it uses a new launch template with the instance metadata options configured, or uses a new version of the current launch template with the instance metadata options configured. For more information, see update-auto-scaling-group.

Examples

- Require the use of IMDSv2
- Deny opt-out of IMDSv2
- Specify maximum hop limit
- Limit who can modify the instance metadata options
- Require role credentials to be retrieved from IMDSv2

Require the use of IMDSv2

The following policy specifies that you can't call the RunInstances API unless the instance is also opted in to require the use of IMDSv2 (indicated by `"ec2:MetadataHttpTokens": "required"`). If you do not specify that the instance requires IMDSv2, you get an `UnauthorizedOperation` error when you call the RunInstances API.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
                {
            "Sid": "RequireImdsV2",
            "Effect": "Deny",
            "Action": "ec2:RunInstances",
            "Resource": "arn:aws-eusc:ec2:*:*:instance/*",
            "Condition": {
```

```
                "StringNotEquals": {
                    "ec2:MetadataHttpTokens": "required"
                }
            }
        }
    ]
}
```

Deny opt-out of IMDSv2

The following policy specifies that you cannot call the `ModifyInstanceMetadataOptions` API and allow the option of IMDSv1 or IMDSv2. If you call the `ModifyInstanceMetadataOptions` API, the `HttpTokens` attribute must be set to `required`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [{
        "Sid": "DenyIMDSv1HttpTokensModification",
        "Effect": "Deny",
        "Action": "ec2:ModifyInstanceMetadataOptions",
        "Resource": "arn:aws-eusc:ec2:*:*:instance/*",
        "Condition": {
            "StringNotEquals": {
                "ec2:Attribute/HttpTokens": "required"
            },
            "Null": {
                "ec2:Attribute/HttpTokens": false
            }
        }
    }]
}
```

Specify maximum hop limit

The following policy specifies that you can't call the RunInstances API unless you also specify a hop limit, and the hop limit can't be more than 3. If you fail to do that, you get an `UnauthorizedOperation` error when you call the RunInstances API.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
                {
            "Sid": "MaxImdsHopLimit",
            "Effect": "Deny",
            "Action": "ec2:RunInstances",
            "Resource": "arn:aws-eusc:ec2:*:*:instance/*",
            "Condition": {
                "NumericGreaterThan": {
                    "ec2:MetadataHttpPutResponseHopLimit": "3"
                }
            }
        }
    ]
}
```

Limit who can modify the instance metadata options

The following policy permits only users with the role `ec2-imds-admins` to make changes to the instance metadata options. If any principal other than the `ec2-imds-admins` role tries to call the ModifyInstanceMetadataOptions API, it will get an `UnauthorizedOperation` error. This statement could be used to control the use of the ModifyInstanceMetadataOptions API; there are currently no fine-grained access controls (conditions) for the ModifyInstanceMetadataOptions API.

Require role credentials to be retrieved from IMDSv2

The following policy specifies that if this policy is applied to a role, and the role is assumed by the EC2 service and the resulting credentials are used to sign a request, then the request must be signed by EC2 role credentials retrieved from IMDSv2. Otherwise, all of its API calls will get an `UnauthorizedOperation` error. This statement/policy can be applied generally because, if the request is not signed by EC2 role credentials, it has no effect.

JSON

```
{
    "Version":"2012-10-17",
```

```
    "Statement": [
              {
            "Sid": "RequireAllEc2RolesToUseV2",
            "Effect": "Deny",
            "Action": "*",
            "Resource": "*",
            "Condition": {
                "NumericLessThan": {
                    "ec2:RoleDelivery": "2.0"
                }
            }
        }
    ]
}
```

Work with Amazon EBS volumes and snapshots

For example policies for working with Amazon EBS volumes and snapshots, see Identity-based policy examples for Amazon EBS.

Example policies to control access to the Amazon EC2 console

You can use IAM policies to grant users the permissions required to work with Amazon EC2. For step-by-step directions, see Creating IAM policies in the *IAM User Guide*.

The console uses additional API actions for its features, so these policies may not work as expected. For example, a user that has permission to use only the `DescribeVolumes` API action will encounter errors when trying to view volumes in the console. This section demonstrates policies that enable users to work with specific parts of the console. For additional information about creating policies for the Amazon EC2 console, see the following AWS Security Blog post: Granting Users Permission to Work in the Amazon EC2 Console.

The following examples show policy statements that you could use to grant users permissions to use Amazon EC2. Replace each *`user input placeholder`* with your own information. These policies are designed for requests that are made using the AWS Management Console. The Amazon EC2 console might call multiple API actions to display a single resource, and it might not be obvious until the user attempts a task and the console displays an error. For more information, see the following AWS Security Blog post: Granting Users Permission to Work in the Amazon EC2 Console.

Examples

- Example: Read-only access
- Example: Use the EC2 launch instance wizard
- Example: Work with security groups
- Example: Work with Elastic IP addresses
- Example: Work with Reserved Instances

To help you work out which API actions are required to perform tasks in the console, you can use a service that logs calls, such as AWS CloudTrail. If your policy does not grant permission to create or modify a specific resource, the console displays an encoded message with diagnostic information. You can decode the message using the DecodeAuthorizationMessage API action for AWS STS, or the decode-authorization-message command in the AWS CLI.

Example: Read-only access

To allow users to view all resources in the Amazon EC2 console, you can use the same policy as the following example: Example: Read-only access. Users cannot perform any actions on those resources or create new resources, unless another statement grants them permission to do so.

View instances, AMIs, and snapshots

Alternatively, you can provide read-only access to a subset of resources. To do this, replace the * wildcard in the `ec2:Describe` API action with specific `ec2:Describe` actions for each resource. The following policy allows users to view all instances, AMIs, and snapshots in the Amazon EC2 console. The `ec2:DescribeTags` action allows users to view public AMIs. The console requires the tagging information to display public AMIs; however, you can remove this action to allow users to view only private AMIs.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": [
         "ec2:DescribeInstances",
         "ec2:DescribeImages",
         "ec2:DescribeTags",
```

```
            "ec2:DescribeSnapshots"
        ],
        "Resource": "*"
    }
    ]
}
```

> **Note**
>
> The Amazon EC2 `ec2:Describe*` API actions do not support resource-level permissions, so you cannot control which individual resources users can view in the console. Therefore, the * wildcard is necessary in the `Resource` element of the above statement. For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

View instances and CloudWatch metrics

The following policy allows users to view instances in the Amazon EC2 console, as well as CloudWatch alarms and metrics in the **Monitoring** tab of the **Instances** page. The Amazon EC2 console uses the CloudWatch API to display the alarms and metrics, so you must grant users permission to use the `cloudwatch:DescribeAlarms`, `cloudwatch:DescribeAlarmsForMetric`, `cloudwatch:ListMetrics`, `cloudwatch:GetMetricStatistics`, and `cloudwatch:GetMetricData` actions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "ec2:DescribeInstances",
            "ec2:DescribeInstanceTypes",
            "cloudwatch:DescribeAlarms",
            "cloudwatch:DescribeAlarmsForMetric",
            "cloudwatch:ListMetrics",
            "cloudwatch:GetMetricStatistics",
            "cloudwatch:GetMetricData"
```

```
      ],
      "Resource": "*"
   }
   ]
}
```

Example: Use the EC2 launch instance wizard

The Amazon EC2 launch instance wizard is a screen with options to configure and launch an instance. Your policy must include permission to use the API actions that allow users to work with the wizard's options. If your policy does not include permission to use those actions, some items in the wizard cannot load properly, and users cannot complete a launch.

Basic launch instance wizard access

To complete a launch successfully, users must be given permission to use the `ec2:RunInstances` API action, and at least the following API actions:

- `ec2:DescribeImages`: To view and select an AMI.
- `ec2:DescribeInstanceTypes`: To view and select an instance type.
- `ec2:DescribeVpcs`: To view the available network options.
- `ec2:DescribeSubnets`: To view all available subnets for the chosen VPC.
- `ec2:DescribeSecurityGroups` or `ec2:CreateSecurityGroup`: To view and select an existing security group, or to create a new one.
- `ec2:DescribeKeyPairs` or `ec2:CreateKeyPair`: To select an existing key pair, or to create a new one.
- `ec2:AuthorizeSecurityGroupIngress`: To add inbound rules.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeInstances",
```

```
                "ec2:DescribeImages",
                "ec2:DescribeInstanceTypes",
                "ec2:DescribeKeyPairs",
                "ec2:DescribeVpcs",
                "ec2:DescribeSubnets",
                "ec2:DescribeSecurityGroups",
                "ec2:CreateSecurityGroup",
                "ec2:AuthorizeSecurityGroupIngress",
                "ec2:CreateKeyPair"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": "*"
        }
    ]
}
```

You can add API actions to your policy to provide more options for users, for example:

- `ec2:DescribeAvailabilityZones`: To view and select a specific Availability Zone.
- `ec2:DescribeNetworkInterfaces`: To view and select existing network interfaces for the selected subnet.
- To add outbound rules to VPC security groups, users must be granted permission to use the `ec2:AuthorizeSecurityGroupEgress` API action. To modify or delete existing rules, users must be granted permission to use the relevant `ec2:RevokeSecurityGroup*` API action.
- `ec2:CreateTags`: To tag the resources that are created by `RunInstances`. For more information, see Grant permission to tag Amazon EC2 resources during creation. If users do not have permission to use this action and they attempt to apply tags on the tagging page of the launch instance wizard, the launch fails.

> **Important**
>
> Specifying a **Name** while launching an instance creates a tag and requires the `ec2:CreateTags` action. Be careful about granting users permission to use the `ec2:CreateTags` action, because doing so limits your ability to use the `aws:ResourceTag` condition key to restrict their use of other resources. If you grant

users permission to use the `ec2:CreateTags` action, they can change a resource's tag to bypass those restrictions. For more information, see Control access using attribute-based access.

- To use Systems Manager parameters when selecting an AMI, you must add `ssm:DescribeParameters` and `ssm:GetParameters` to your policy. `ssm:DescribeParameters` grants your users the permission to view and select Systems Manager parameters. `ssm:GetParameters` grants your users the permission to get the values of the Systems Manager parameters. You can also restrict access to specific Systems Manager parameters. For more information, see **Restrict access to specific Systems Manager parameters** later in this section.

Currently, the Amazon EC2 `Describe*` API actions do not support resource-level permissions, so you cannot restrict which individual resources users can view in the launch instance wizard. However, you can apply resource-level permissions on the `ec2:RunInstances` API action to restrict which resources users can use to launch an instance. The launch fails if users select options that they are not authorized to use.

Restrict access to a specific instance type, subnet, and Region

The following policy allows users to launch `t2.micro` instances using AMIs owned by Amazon, and only into a specific subnet (`subnet-1a2b3c4d`). Users can only launch in the specified Region. If users select a different Region, or select a different instance type, AMI, or subnet in the launch instance wizard, the launch fails.

The first statement grants users permission to view the options in the launch instance wizard or to create new ones, as explained in the example above. The second statement grants users permission to use the network interface, volume, key pair, security group, and subnet resources for the `ec2:RunInstances` action, which are required to launch an instance into a VPC. For more information about using the `ec2:RunInstances` action, see Launch instances (RunInstances). The third and fourth statements grant users permission to use the instance and AMI resources respectively, but only if the instance is a `t2.micro` instance, and only if the AMI is owned by Amazon, or certain trusted and verified partners.

JSON

```
{
   "Version":"2012-10-17",
```

```
    "Statement": [{
       "Effect": "Allow",
       "Action": [
          "ec2:DescribeInstances",
          "ec2:DescribeImages",
          "ec2:DescribeInstanceTypes",
          "ec2:DescribeKeyPairs",
          "ec2:CreateKeyPair",
          "ec2:DescribeVpcs",
          "ec2:DescribeSubnets", "ec2:DescribeSecurityGroups",
          "ec2:CreateSecurityGroup",
          "ec2:AuthorizeSecurityGroupIngress"
    ],
    "Resource": "*"
    },
    {
       "Effect": "Allow",
       "Action":"ec2:RunInstances",
       "Resource": [
          "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:network-interface/*",
          "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:volume/*",
          "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:key-pair/*",
          "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group/*",
          "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:subnet/subnet-1a2b3c4d"
       ]
    },
    {
       "Effect": "Allow",
       "Action": "ec2:RunInstances",
       "Resource": [
          "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/*"
       ],
       "Condition": {
          "StringEquals": {
             "ec2:InstanceType": "t2.micro"
          }
       }
    },
    {
       "Effect": "Allow",
       "Action": "ec2:RunInstances",
       "Resource": [
             "arn:aws-eusc:ec2:eusc-de-east-1::image/ami-*"
       ],
```

```
      "Condition": {
         "StringEquals": {
            "ec2:Owner": "amazon"
         }
      }
   }
   ]
}
```

Restrict access to specific Systems Manager parameters

The following policy grants access to use Systems Manager parameters with a specific name.

The first statement grants users the permission to view Systems Manager parameters when selecting an AMI in the launch instance wizard. The second statement grants users the permission to only use parameters that are named `prod-*`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": [
         "ssm:DescribeParameters"
      ],
      "Resource": "*"
   },
   {
      "Effect": "Allow",
      "Action": [
         "ssm:GetParameters"
      ],
     "Resource": "arn:aws-eusc:ssm:eusc-de-east-1:123456123456:parameter/prod-*"
   }
   ]
}
```

Example: Work with security groups

View security groups and add and remove rules

The following policy grants users permission to view security groups in the Amazon EC2 console, to add and remove inbound and outbound rules, and to list and modify rule descriptions for existing security groups that have the tag `Department=Test`.

In the first statement, the `ec2:DescribeTags` action allows users to view tags in the console, which makes it easier for users to identify the security groups that they are allowed to modify.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": [
         "ec2:DescribeSecurityGroups",
         "ec2:DescribeSecurityGroupRules",
         "ec2:DescribeTags"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:AuthorizeSecurityGroupIngress",
         "ec2:RevokeSecurityGroupIngress",
         "ec2:AuthorizeSecurityGroupEgress",
         "ec2:RevokeSecurityGroupEgress",
         "ec2:ModifySecurityGroupRules",
         "ec2:UpdateSecurityGroupRuleDescriptionsIngress",
         "ec2:UpdateSecurityGroupRuleDescriptionsEgress"
      ],
      "Resource": [
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group/*"
      ],
      "Condition": {
         "StringEquals": {
            "aws:ResourceTag/Department": "Test"
         }
```

```
      }
   },
   {
      "Effect": "Allow",
      "Action": [
         "ec2:ModifySecurityGroupRules"
      ],
      "Resource": [
         "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group-rule/*"
      ]
   }
]}
```

Work with the Create Security Group dialog box

You can create a policy that allows users to work with the **Create Security Group** dialog box in the Amazon EC2 console. To use this dialog box, users must be granted permission to use at the least the following API actions:

- `ec2:CreateSecurityGroup`: To create a new security group.
- `ec2:DescribeVpcs`: To view a list of existing VPCs in the **VPC** list.

With these permissions, users can create a new security group successfully, but they cannot add any rules to it. To work with rules in the **Create Security Group** dialog box, you can add the following API actions to your policy:

- `ec2:AuthorizeSecurityGroupIngress`: To add inbound rules.
- `ec2:AuthorizeSecurityGroupEgress`: To add outbound rules to VPC security groups.
- `ec2:RevokeSecurityGroupIngress`: To modify or delete existing inbound rules. This is useful to allow users to use the **Copy to new** feature in the console. This feature opens the **Create Security Group** dialog box and populates it with the same rules as the security group that was selected.
- `ec2:RevokeSecurityGroupEgress`: To modify or delete outbound rules for VPC security groups. This is useful to allow users to modify or delete the default outbound rule that allows all outbound traffic.
- `ec2:DeleteSecurityGroup`: To cater for when invalid rules cannot be saved. The console first creates the security group, and then adds the specified rules. If the rules are invalid, the action

fails, and the console attempts to delete the security group. The user remains in the **Create Security Group** dialog box so that they can correct the invalid rule and try to create the security group again. This API action is not required, but if a user is not granted permission to use it and attempts to create a security group with invalid rules, the security group is created without any rules, and the user must add them afterward.

- `ec2:UpdateSecurityGroupRuleDescriptionsIngress`: To add or update descriptions of ingress (inbound) security group rules.
- `ec2:UpdateSecurityGroupRuleDescriptionsEgress`: To add or update descriptions of egress (outbound) security group rules.
- `ec2:ModifySecurityGroupRules`: To modify security group rules.
- `ec2:DescribeSecurityGroupRules`: To list security group rules.

The following policy grants users permission to use the **Create Security Group** dialog box, and to create inbound and outbound rules for security groups that are associated with a specific VPC (`vpc-1a2b3c4d`). Users can create security groups for a VPC, but they cannot add any rules to them. Similarly, users cannot add any rules to any existing security group that's not associated with VPC `vpc-1a2b3c4d`. Users are also granted permission to view all security groups in the console. This makes it easier for users to identify the security groups to which they can add inbound rules. This policy also grants users permission to delete security groups that are associated with VPC `vpc-1a2b3c4d`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeSecurityGroups",
        "ec2:CreateSecurityGroup",
        "ec2:DescribeVpcs"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DeleteSecurityGroup",
```

```
        "ec2:AuthorizeSecurityGroupIngress",
        "ec2:AuthorizeSecurityGroupEgress"
      ],
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:security-group/
*",
      "Condition":{
         "ArnEquals": {
            "ec2:Vpc": "arn:aws-eusc:ec2:eusc-de-
east-1:111122223333:vpc/vpc-1a2b3c4d"
         }
      }
    }
   ]
}
```

Example: Work with Elastic IP addresses

To allow users to view Elastic IP addresses in the Amazon EC2 console, you must grant users permission to use the `ec2:DescribeAddresses` action.

To allow users to work with Elastic IP addresses, you can add the following actions to your policy.

- `ec2:AllocateAddress`: To allocate an Elastic IP address.
- `ec2:ReleaseAddress`: To release an Elastic IP address.
- `ec2:AssociateAddress`: To associate an Elastic IP address with an instance or a network interface.
- `ec2:DescribeNetworkInterfaces` and `ec2:DescribeInstances`: To work with the **Associate address** screen. The screen displays the available instances or network interfaces to which you can associate an Elastic IP address.
- `ec2:DisassociateAddress`: To disassociate an Elastic IP address from an instance or a network interface.

The following policy allows users to view, allocate, and associate Elastic IP addresses with instances. Users cannot associate Elastic IP addresses with network interfaces, disassociate Elastic IP addresses, or release them.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeAddresses",
                "ec2:AllocateAddress",
                "ec2:DescribeInstances",
                "ec2:AssociateAddress"
            ],
            "Resource": "*"
        }
    ]
}
```

Example: Work with Reserved Instances

The following policy allows users to view and modify Reserved Instances in your account, as well as purchase new Reserved Instances in the AWS Management Console.

This policy allows users to view all the Reserved Instances, as well as On-Demand Instances, in the account. It's not possible to set resource-level permissions for individual Reserved Instances.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": [
         "ec2:DescribeReservedInstances",
         "ec2:ModifyReservedInstances",
         "ec2:PurchaseReservedInstancesOffering",
         "ec2:DescribeInstances",
         "ec2:DescribeInstanceTypes",
         "ec2:DescribeAvailabilityZones",
         "ec2:DescribeReservedInstancesOfferings"
```

```
      ],
      "Resource": "*"
   }
   ]
}
```

The `ec2:DescribeAvailabilityZones` action is necessary to ensure that the Amazon EC2 console can display information about the Availability Zones in which you can purchase Reserved Instances. The `ec2:DescribeInstances` action is not required, but ensures that the user can view the instances in the account and purchase reservations to match the correct specifications.

You can adjust the API actions to limit user access, for example removing `ec2:DescribeInstances` and `ec2:DescribeAvailabilityZones` means the user has read-only access.

AWS managed policies for Amazon EC2

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the *IAM User Guide*.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the **ReadOnlyAccess** AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the *IAM User Guide*.

AWS managed policy: AmazonEC2FullAccess

You can attach the `AmazonEC2FullAccess` policy to your IAM identities. This policy grants permissions that allow full access to Amazon EC2.

To view the permissions for this policy, see AmazonEC2FullAccess in the *AWS Managed Policy Reference*.

AWS managed policy: AmazonEC2ReadOnlyAccess

You can attach the `AmazonEC2ReadOnlyAccess` policy to your IAM identities. This policy grants permissions that allow read-only access to Amazon EC2.

To view the permissions for this policy, see AmazonEC2ReadOnlyAccess in the *AWS Managed Policy Reference*.

AWS managed policy: AmazonEC2ImageReferencesAccessPolicy

You can attach the `AmazonEC2ImageReferencesAccessPolicy` policy to your IAM identities. This policy grants the permissions needed to use the EC2 DescribeImageReferences API, including permission to view EC2 instances, launch templates, Systems Manager parameters, and Image Builder recipes. The policy supports the `IncludeAllResourceTypes` flag and will continue to work when AWS adds support for new resource types, removing the need for future policy updates.

To view the permissions for this policy, see AmazonEC2ImageReferencesAccessPolicy in the *AWS Managed Policy Reference*.

AWS managed policy: AWSEC2CapacityReservationFleetRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForEC2CapacityReservationFleet** to allow the service to create, modify, and cancel Capacity Reservations in a Capacity Reservation Fleet on your behalf. For more information, see Using service-linked roles for Capacity Reservation Fleet.

To view the permissions for this policy, see AWSEC2CapacityReservationFleetRolePolicy in the *AWS Managed Policy Reference*.

AWS managed policy: AWSEC2FleetServiceRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForEC2Fleet** to allow EC2 Fleet to request, launch, terminate, and tag instances on your behalf. For more information, see Service-linked role for EC2 Fleet.

To view the permissions for this policy, see AWSEC2FleetServiceRolePolicy in the *AWS Managed Policy Reference*.

AWS managed policy: AWSEC2SpotFleetServiceRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForEC2SpotFleet** to allow Spot Fleet to launch and manage instances on your behalf. For more information, see Service-linked role for Spot Fleet.

To view the permissions for this policy, see AWSEC2SpotFleetServiceRolePolicy in the *AWS Managed Policy Reference*.

AWS managed policy: AWSEC2SpotServiceRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForEC2Spot** to allow Amazon EC2 to launch and manage Spot Instances on your behalf. For more information, see Service-linked role for Spot Instance requests.

To view the permissions for this policy, see AWSEC2SpotServiceRolePolicy in the *AWS Managed Policy Reference*.

AWS managed policy: AWSEC2VssSnapshotPolicy

You can attach this managed policy to the IAM instance profile role that you use for your Amazon EC2 Windows instances. The policy grants permissions to allow Amazon EC2 to create and manage VSS snapshots on your behalf.

To view the permissions for this policy, see AWSEC2VssSnapshotPolicy in the *AWS Managed Policy Reference*.

AWS managed policy: DeclarativePoliciesEC2Report

This policy is attached to the service-linked role named `AWSServiceRoleForDeclarativePoliciesEC2Report` to provide access to read-only APIs needed to generate the account status report for declarative policies.

To view the permissions for this policy, see DeclarativePoliciesEC2Report in the *AWS Managed Policy Reference*.

AWS managed policy: EC2FastLaunchFullAccess

You can attach the `EC2FastLaunchFullAccess` policy to your instance profile or other IAM role. This policy grants full access to EC2 Fast Launch actions, and targeted permissions as follows.

Permissions details

- **EC2 Fast Launch** – Administrative access is granted, so that the role can enable or disable EC2 Fast Launch, and describe EC2 Fast Launch images.
- **Amazon EC2** – Access is granted for Amazon EC2 RunInstances, CreateTags, Describe, and Create and Modify Launch Template operations. Access is also granted to create network and security group resources, authorize ingress rules, and delete resources that EC2 Fast Launch created.
- **IAM** – Access is granted to get and use instance profiles whose name contains `ec2fastlaunch` to create the EC2FastLaunchServiceRolePolicy service-linked role.
- **CloudFormation** – Access is granted for EC2 Fast Launch to describe and create CloudFormation stacks, and to delete stacks that it created.

To view the permissions for this policy, see EC2FastLaunchFullAccess in the *AWS Managed Policy Reference*.

AWS managed policy: AWSEC2CapacityManagerServiceRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForEC2CapacityManager** to allow EC2 Capacity Manager to manage capacity resources and integrate with AWS Organizations on your behalf. For more information, see Service-linked roles for EC2 Capacity Manager.

To view the permissions for this policy, see AWSEC2CapacityManagerServiceRolePolicy in the *AWS Managed Policy Reference*.

AWS managed policy: EC2FastLaunchServiceRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForEC2FastLaunch** to allow Amazon EC2 to create and manage a set of pre-provisioned snapshots that reduce the time it takes to launch instances from your EC2 Fast Launch-enabled AMI. For more information, see the section called “Service-linked role”.

To view the permissions for this policy, see EC2FastLaunchServiceRolePolicy in the *AWS Managed Policy Reference*.

AWS managed policy: Ec2InstanceConnect

You can attach the `Ec2InstanceConnect` policy to your IAM identities. This policy grants permissions that allows customers to call EC2 Instance Connect to publish ephemeral keys to their EC2 instances and connect through SSH or the EC2 Instance Connect CLI.

To view the permissions for this policy, see Ec2InstanceConnect in the *AWS Managed Policy Reference*.

AWS managed policy: Ec2InstanceConnectEndpoint

This policy is attached to a service-linked role named **AWSServiceRoleForEC2InstanceConnect** to allow EC2 Instance Connect Endpoint to perform actions on your behalf. For more information, see Service-linked role for EC2 Instance Connect Endpoint.

To view the permissions for this policy, see Ec2InstanceConnectEndpoint in the *AWS Managed Policy Reference*. For a description of the updates to this policy, see Amazon EC2 updates to AWS managed policies.

Amazon EC2 updates to AWS managed policies

View details about updates to AWS managed policies for Amazon EC2 since this service began tracking these changes.

Change	Description	Date
AWSEC2CapacityManagerServiceRolePolicy – New policy	Amazon EC2 added this policy to allow you to manage capacity resources and integrate with AWS Organizations on your behalf.	October 15, 2025
AmazonEC2ImageReferencesAccessPolicy – New policy	Amazon EC2 added this policy to provide permission to scan all resources types supported by the EC2 DescribeImageReferences API.	August 26, 2025
Ec2InstanceConnectEndpoint – Updated policy	To support the modification of existing Instance Connect	July 31, 2025

Change	Description	Date
	Endpoints, Amazon EC2 updated this policy to add permissions to assign and unassign IPv6 addresses and modify security groups on network interfaces created by EC2 Instance Connect Endpoint. Amazon EC2 also updated this policy to replace the `Null` condition operator with the `StringLike` condition operator.	
EC2FastLaunchServiceRolePolicy – Updated policy	To help prevent orphaned resources, Amazon EC2 updated this policy to add permission to describe volumes, volume attributes and network interfaces, and to delete volumes and network interfaces that EC2 Fast Launch created.	July 17, 2025
EC2FastLaunchFullAccess – Updated policy	Amazon EC2 updated this policy to include Create and Modify Launch Template operations, to create network and security group resources, authorize ingress rules, and delete resources that EC2 Fast Launch created. It can additionally describe and create CloudFormation stacks, and delete stacks that EC2 Fast Launch created.	May 14, 2025

Change	Description	Date
EC2FastLaunchServiceRolePolicy – Updated policy	Amazon EC2 updated this policy to add Amazon EventBridge access to create and manage event rules for EC2 Fast Launch. Additionally, EC2 Fast Launch can now describe CloudFormation stacks, launch an instance from an AMI that's associated with AWS License Manager, get a list of AWS KMS grants it created that can be retired, and delete launch templates that it created.	May 14, 2025
AWSEC2CapacityReservationFleetRolePolicy – Updated permissions	Amazon EC2 updated the `AWSEC2CapacityReservationFleetRolePolicy` managed policy to use the `ArnLike` condition operator instead of the `StringLike` condition operator.	March 03, 2025
AmazonEC2ReadOnlyAccess – Added permissions	Amazon EC2 added a permission that allows you to retrieve security groups using the `GetSecurityGroupsForVpc` operation.	December 27, 2024

Change	Description	Date
EC2FastLaunchFullAccess – New policy	Amazon EC2 added this policy to perform API actions related to the EC2 Fast Launch feature from an instance. The policy can be attached to the instance profile for an instance that's launched from a EC2 Fast Launch enabled AMI.	May 14, 2024
AWSEC2VssSnapshotPolicy – New policy	Amazon EC2 added the `AWSEC2VssSnapshotPolicy` policy that contains permissions to create and add tags to Amazon Machine Images (AMIs) and EBS snapshots.	March 28, 2024
Ec2InstanceConnectEndpoint – New policy	Amazon EC2 added the `Ec2InstanceConnectEndpoint` policy. This policy is attached to the **AWSServiceRoleForEC2InstanceConnect** service-linked role, to allow Amazon EC2 to perform actions on your behalf when you create an EC2 Instance Connect Endpoint.	January 24, 2023

Change	Description	Date
EC2FastLaunchServiceRolePolicy – New policy	Amazon EC2 added the EC2 Fast Launch feature to enable Windows AMIs to launch instances faster by creating a set of pre-provisioned snapshots.	November 26, 2021
Amazon EC2 started tracking changes	Amazon EC2 started tracking changes to its AWS managed policies	March 1, 2021

IAM roles for Amazon EC2

Applications must sign their API requests with AWS credentials. Therefore, if you are an application developer, you need a strategy for managing credentials for your applications that run on EC2 instances. For example, you can securely distribute your AWS credentials to the instances, enabling the applications on those instances to use your credentials to sign requests, while protecting your credentials from other users. However, it's challenging to securely distribute credentials to each instance, especially those that AWS creates on your behalf, such as Spot Instances or instances in Auto Scaling groups. You must also be able to update the credentials on each instance when you rotate your AWS credentials.

We designed IAM roles so that your applications can securely make API requests from your instances, without requiring you to manage the security credentials that the applications use. Instead of creating and distributing your AWS credentials, you can delegate permission to make API requests using IAM roles as follows:

1. Create an IAM role.
2. Define which accounts or AWS services can assume the role.
3. Define which API actions and resources the application can use after assuming the role.
4. Specify the role when you launch your instance, or attach the role to an existing instance.
5. Have the application retrieve a set of temporary credentials and use them.

For example, you can use IAM roles to grant permissions to applications running on your instances that need to use a bucket in Amazon S3. You can specify permissions for IAM roles by creating a policy in JSON format. These are similar to the policies that you create for users. If you change a role, the change is propagated to all instances.

> **Note**
>
> Amazon EC2 IAM role credentials are not subject to maximum session durations configured in the role. For more information, see Methods to assume a role in the *IAM User Guide*.

When creating IAM roles, associate least privilege IAM policies that restrict access to the specific API calls the application requires. For Windows-to-Windows communication, use well-defined and well-documented Windows groups and roles to grant application-level access between Windows instances. Groups and roles allow customers to define least privilege application and NTFS folder-level permissions to limit access to application-specific requirements.

You can only attach one IAM role to an instance, but you can attach the same role to many instances. For more information about creating and using IAM roles, see Roles in the *IAM User Guide*.

You can apply resource-level permissions to your IAM policies to control the users' ability to attach, replace, or detach IAM roles for an instance. For more information, see Supported resource-level permissions for Amazon EC2 API actions and the following example: Example: Work with IAM roles.

Contents

- Instance profiles
- Permissions for your use case
- Retrieve security credentials from instance metadata
- Grant permissions to attach an IAM role to an instance
- Attach an IAM role to an instance
- Instance identity roles for Amazon EC2 instances

Instance profiles

Amazon EC2 uses an *instance profile* as a container for an IAM role. When you create an IAM role using the IAM console, the console creates an instance profile automatically and gives it the same

name as the role to which it corresponds. If you use the Amazon EC2 console to launch an instance with an IAM role or to attach an IAM role to an instance, you choose the role based on a list of instance profile names.

If you use the AWS CLI, API, or an AWS SDK to create a role, you create the role and instance profile as separate actions, with potentially different names. If you then use the AWS CLI, API, or an AWS SDK to launch an instance with an IAM role or to attach an IAM role to an instance, specify the instance profile name.

An instance profile can contain only one IAM role. You can include an IAM role in multiple instance profiles.

To update permissions for an instance, replace its instance profile. We do not recommend removing a role from an instance profile, because there is a delay of up to one hour before this change takes effect.

For more information, see Use instance profiles in the *IAM User Guide*.

Permissions for your use case

When you first create an IAM role for your applications, you might sometimes grant permissions beyond what is required. Before launching your application in your production environment, you can generate an IAM policy that is based on the access activity for an IAM role. IAM Access Analyzer reviews your AWS CloudTrail logs and generates a policy template that contains the permissions that have been used by the role in your specified date range. You can use the template to create a managed policy with fine-grained permissions and then attach it to the IAM role. That way, you grant only the permissions that the role needs to interact with AWS resources for your specific use case. This helps you adhere to the best practice of granting least privilege. For more information, see IAM Access Analyzer policy generation in the *IAM User Guide*.

Retrieve security credentials from instance metadata

An application on the instance retrieves the security credentials provided by the role from the instance metadata item `iam/security-credentials/`*role-name*. The application is granted the permissions for the actions and resources that you've defined for the role through the security credentials associated with the role. These security credentials are temporary and we rotate them automatically. We make new credentials available at least five minutes before the expiration of the old credentials.

For more information about instance metadata, see Use instance metadata to manage your EC2 instance.

> **Warning**
>
> If you use services that use instance metadata with IAM roles, ensure that you don't expose your credentials when the services make HTTP calls on your behalf. The types of services that could expose your credentials include HTTP proxies, HTML/CSS validator services, and XML processors that support XML inclusion.

For your Amazon EC2 workloads, we recommend that you retrieve session credentials using the method described below. These credentials should enable your workload to make AWS API requests, without needing to use `sts:AssumeRole` to assume the same role that is already associated with the instance. Unless you need to pass session tags for attribute-based access control (ABAC) or pass a session policy to further restrict permissions of the role, such role assumption calls are unnecessary as they create a new set of the same temporary role session credentials.

If your workload uses a role to assume itself, you must create a trust policy that explicitly allows that role to assume itself. If you do not create the trust policy, you get an `AccessDenied` error. For more information, see Update a role trust policy in the *IAM User Guide*.

IMDSv2

Linux

Run the following command from your Linux instance to retrieve the security credentials for an IAM role.

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
    && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/iam/security-credentials/role-name
```

Windows

Run the following cmdlet from your Windows instance to retrieve the security credentials for an IAM role.

```
[string]$token = Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} `
    -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token" = $token} `
    -Method GET -Uri http://169.254.169.254/latest/meta-data/iam/security-
credentials/role-name
```

IMDSv1

Linux

Run the following command from your Linux instance to retrieve the security credentials for an IAM role.

```
curl http://169.254.169.254/latest/meta-data/iam/security-credentials/role-name
```

Windows

Run the following cmdlet from your Windows instance to retrieve the security credentials for an IAM role.

```
Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/iam/security-
credentials/role-name
```

The following is example output. If you are not able to retrieve the security credentials, see I can't access the temporary security credentials on my EC2 instance in the *IAM User Guide*.

```
{
  "Code" : "Success",
  "LastUpdated" : "2012-04-26T16:39:16Z",
  "Type" : "AWS-HMAC",
  "AccessKeyId" : "ASIAIOSFODNN7EXAMPLE",
  "SecretAccessKey" : "wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY",
  "Token" : "token",
  "Expiration" : "2017-05-17T15:09:54Z"
}
```

For applications, AWS CLI, and Tools for Windows PowerShell commands that run on the instance, you do not have to explicitly get the temporary security credentials—the AWS SDKs, AWS CLI, and Tools for Windows PowerShell automatically get the credentials from the EC2 instance metadata service and use them. To make a call outside of the instance using temporary security credentials (for example, to test IAM policies), you must provide the access key, secret key, and the session token. For more information, see Using Temporary Security Credentials to Request Access to AWS Resources in the *IAM User Guide*.

Grant permissions to attach an IAM role to an instance

The identities in your AWS account, such as IAM users, must have specific permissions to launch an Amazon EC2 instance with an IAM role, attach an IAM role to an instance, replace the IAM role for an instance, or detach an IAM role from an instance. You must grant permission to use the following API actions as required:

- `iam:PassRole`
- `ec2:AssociateIamInstanceProfile`
- `ec2:DisassociateIamInstanceProfile`
- `ec2:ReplaceIamInstanceProfileAssociation`

> **Note**
>
> If you specify the resource for `iam:PassRole` as `*`, this would grant access to pass any of your IAM roles to an instance. To follow the best practice of least privilege, specify the ARNs of specific IAM roles with `iam:PassRole`, as shown in the example policy below.

Example policy for programmatic access

The following IAM policy grants permissions to launch instances with an IAM role, attach an IAM role to an instance, or replace the IAM role for an instance using the AWS CLI or the Amazon EC2 API.

JSON

```
{
  "Version":"2012-10-17",
```

```
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances",
         "ec2:AssociateIamInstanceProfile",
         "ec2:DisassociateIamInstanceProfile",
         "ec2:ReplaceIamInstanceProfileAssociation"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws-eusc:iam::123456789012:role/DevTeam*"
    }
  ]
}
```

Additional requirement for console access

To grant permissions to complete the same tasks using the Amazon EC2 console, you must also include the `iam:ListInstanceProfiles` API action.

Attach an IAM role to an instance

You can create an IAM role and attach it to an instance during or after launch. You can also replace or detach IAM roles.

Creating and attaching an IAM role during instance launch (Recommended)

1. During EC2 instance launch, expand **Advanced details**.
2. In the **IAM instance profile** section, choose **Create new IAM role**.
3. An inline role creation form opens, allowing you to:

   - Specify **Role name** (for example, `EC2-S3-Access-Role`)
   - Define permissions by selecting AWS managed policies or creating custom policies for your instance

     For example, to grant S3 access, select the `AmazonS3ReadOnlyAccess` managed policy

- Review the trust policy that allows `ec2.amazonaws.com` to assume the role
- Add optional tags for metadata

4. Choose **Create role**.

   The newly created role is automatically selected and will be attached to your instance through an instance profile when the instance launches.

> **Note**
>
> When you create a role using the console during instance launch, an instance profile with the same name as the role is automatically created. The instance profile is a container that passes IAM role information to the instance at launch.

> **Important**
>
> - You can only attach one IAM role to an instance, but you can attach the same role to many instances.
> - Associate least privilege IAM policies that restrict access to the specific API calls the application requires.

For more information about creating and using IAM roles, see Roles in the *IAM User Guide*.

Attaching an existing IAM role during instance launch

To attach an existing IAM role to an instance at launch using the Amazon EC2 console, expand **Advanced details**. For **IAM instance profile**, select the IAM role from the dropdown list.

> **Note**
>
> If you created your IAM role using the IAM console, the instance profile was created for you and given the same name as the role. If you created your IAM role using the AWS CLI, API, or an AWS SDK, you might have given your instance profile a different name than the role.

You can attach an IAM role to an instance that is running or stopped. If the instance already has an IAM role attached, you must replace it with the new IAM role.

Console

To attach an IAM role to an instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Security**, **Modify IAM role**.
5. For **IAM role**, select the IAM instance profile.
6. Choose **Update IAM role**.

AWS CLI

To attach an IAM role to an instance

Use the associate-iam-instance-profile command to attach the IAM role to the instance. When you specify the instance profile, you can use either the Amazon Resource Name (ARN) of the instance profile, or you can use its name.

```
aws ec2 associate-iam-instance-profile \
    --instance-id i-1234567890abcdef0 \
    --iam-instance-profile Name="TestRole-1"
```

PowerShell

To attach an IAM role to an instance

Use the Register-EC2IamInstanceProfile cmdlet.

```
Register-EC2IamInstanceProfile `
    -InstanceId i-1234567890abcdef0 `
    -IamInstanceProfile_Name TestRole-1
```

To replace the IAM role on an instance that already has an attached IAM role, the instance must be running. You can do this if you want to change the IAM role for an instance without detaching

the existing one first. For example, you can do this to ensure that API actions performed by applications running on the instance are not interrupted.

Console

To replace an IAM role for an instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Security**, **Modify IAM role**.
5. For **IAM role**, select the IAM instance profile.
6. Choose **Update IAM role**.

AWS CLI

To replace an IAM role for an instance

1. If required, use the describe-iam-instance-profile-associations command to get the association ID.

```
aws ec2 describe-iam-instance-profile-associations \
    --filters Name=instance-id,Values=i-1234567890abcdef0 \
    --query IamInstanceProfileAssociations.AssociationId
```

2. Use the replace-iam-instance-profile-association command. Specify the association ID for the existing instance profile and the ARN or name of the new instance profile.

```
aws ec2 replace-iam-instance-profile-association \
    --association-id iip-assoc-0044d817db6c0a4ba \
    --iam-instance-profile Name="TestRole-2"
```

PowerShell

To replace an IAM role for an instance

1. If required, use the Get-EC2IamInstanceProfileAssociation cmdlet to get the association ID.

```
(Get-EC2IamInstanceProfileAssociation -Filter @{Name="instance-id";
 Values="i-0636508011d8e966a"}).AssociationId
```

2. Use the Set-EC2IamInstanceProfileAssociation cmdlet. Specify the association ID for the existing instance profile and the ARN or name of the new instance profile.

```
Set-EC2IamInstanceProfileAssociation `
    -AssociationId iip-assoc-0044d817db6c0a4ba `
    -IamInstanceProfile_Name TestRole-2
```

You can detach an IAM role from an instance that is running or stopped.

Console

To detach an IAM role from an instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Security**, **Modify IAM role**.
5. For **IAM role**, choose **No IAM Role**.
6. Choose **Update IAM role**.
7. When promoted for confirmation, enter **Detach**, and then choose **Detach**.

AWS CLI

To detach an IAM role from an instance

1. If required, use describe-iam-instance-profile-associations to get the association ID for the IAM instance profile to detach.

```
aws ec2 describe-iam-instance-profile-associations \
    --filters Name=instance-id,Values=i-1234567890abcdef0 \
    --query IamInstanceProfileAssociations.AssociationId
```

2. Use the disassociate-iam-instance-profile command.

```
aws ec2 disassociate-iam-instance-profile --association-id iip-
assoc-0044d817db6c0a4ba
```

PowerShell

To detach an IAM role from an instance

1. If required, use Get-EC2IamInstanceProfileAssociation to get the association ID for the IAM instance profile to detach.

```
(Get-EC2IamInstanceProfileAssociation -Filter @{Name="instance-id";
 Values="i-0636508011d8e966a"}).AssociationId
```

2. Use the Unregister-EC2IamInstanceProfile cmdlet.

```
Unregister-EC2IamInstanceProfile -AssociationId iip-assoc-0044d817db6c0a4ba
```

Instance identity roles for Amazon EC2 instances

Each Amazon EC2 instance that you launch has an *instance identity role* that represents its identity. An instance identity role is a type of IAM role. AWS services and features that are integrated to use the instance identity role can use it to identify the instance to the service.

The instance identity role credentials are accessible from the Instance Metadata Service (IMDS) at `/identity-credentials/ec2/security-credentials/ec2-instance`. The credentials consist of an AWS temporary access key pair and a session token. They are used to sign AWS Sigv4 requests to the AWS services that use the instance identity role. The credentials are present in the instance metadata regardless of whether a service or feature that makes use of instance identity roles is enabled on the instance.

Instance identity roles are automatically created when an instance is launched, have no role-trust policy document, and are not subject to any identity or resource policy.

Supported services

The following AWS services use the instance identity role:

- **Amazon Bedrock AgentCore** – AgentCore Runtime Instances use the instance identity role for setting up the instances during launch.
- **Amazon EC2** – EC2 Instance Connect uses the instance identity role to update the host keys for a Linux instance.
- **Amazon GuardDuty** – GuardDuty Runtime Monitoring uses the instance identity role to allow the runtime agent to send security telemetry to the GuardDuty VPC endpoint.
- **AWS Lambda** – Lambda Managed Instances uses the instance identity role for lifecycle hooks, telemetry, and artifact distribution.
- **AWS Security Token Service (AWS STS)** – Instance identity role credentials can be used with the AWS STS `GetCallerIdentity` action.
- **AWS Systems Manager** – When using Default Host Management Configuration, AWS Systems Manager uses the identity provided by the instance identity role to register EC2 instances. After identifying your instance, Systems Manager can pass your `AWSSystemsManagerDefaultEC2InstanceManagementRole` IAM role to your instance.

Instance identity roles can't be used with other AWS services or features because they do not have an integration with instance identity roles.

Instance identity role ARN

The instance identity role ARN takes the following format:

```
arn:aws-partition:iam::account-number:assumed-role/aws:ec2-instance/instance-id
```

For example:

```
arn:aws:iam::0123456789012:assumed-role/aws:ec2-instance/i-1234567890abcdef0
```

For more information about ARNs, see Amazon Resource Names (ARNs) in the *IAM User Guide*.

Update management for Amazon EC2 instances

We recommend that you regularly patch, update, and secure the operating system and applications on your EC2 instances. You can use AWS Systems Manager Patch Manager to automate the process of installing security-related updates for both the operating system and applications.

For EC2 instances in an Auto Scaling group, you can use the AWS-PatchAsgInstance runbook to help avoid instances that are undergoing patching from being replaced. Alternatively, you can use any automatic update services or recommended processes for installing updates that are provided by the application vendor.

Resources

- **AL2023** – Updating AL2023 in the *Amazon Linux 2023 User Guide*
- **AL2** – Manage software on your Amazon Linux 2 instance in the *Amazon Linux 2 User Guide*
- **Windows instances** – the section called "Update management"

Security best practices for Windows instances

We recommend that you follow these security best practices for your Windows instances.

Contents

- High-level security best practices
- Update management
- Configuration management
- Change management
- Audit and accountability for Amazon EC2 Windows instances

High-level security best practices

You should adhere to the following high-level security best practices for your Windows instances:

- **Least access** – Grant access only to systems and locations that are trusted and expected. This applies to all Microsoft products such as Active Directory, Microsoft business productivity servers, and infrastructure services such as Remote Desktop Services, reverse proxy servers, IIS web servers,and more. Use AWS capabilities such as Amazon EC2 instance security groups, network access control lists (ACLs), and Amazon VPC public/private subnets to layer security across multiple locations in an architecture. Within a Windows instance, customers can use Windows Firewall to further layer a defense-in-depth strategy within their deployment. Install only the OS components and applications that are necessary for the system to function as designed. Configure infrastructure services such as IIS to run under service accounts, or to use features such as application pool identities to access resources locally and remotely across your infrastructure.

- **Least privilege** – Determine the minimum set of privileges that instances and accounts need to perform their functions. Restrict these servers and users to only allow these defined permissions. Use techniques such as Role Based Access Controls to reduce the surface area of administrative accounts, and create the most limited roles to accomplish a task. Use OS features such as Encrypting File System (EFS) within NTFS to encrypt sensitive data at rest, and control application and user access to it.
- **Configuration management** – Create a baseline server configuration that incorporates up-to-date security patches and host-based protection suites that include anti-virus, anti-malware, intrusion detection/prevention, and file integrity monitoring. Assess each server against the current recorded baseline to identify and flag any deviations. Ensure each server is configured to generate and securely store appropriate log and audit data.
- **Change management** – Create processes to control changes to server configuration baselines and work toward fully automated change processes. Also, leverage Just Enough Administration (JEA) with Windows PowerShell DSC to limit administrative access to the minimum required functions.
- **Patch management** – Implement processes that regularly patch, update, and secure the operating system and applications on your EC2 instances.
- **Audit logs** – Audit access and all changes to Amazon EC2 instances to verify server integrity and ensure only authorized changes are made. Leverage features such as Enhanced Logging for IIS to enhance default logging capabilities. AWS capabilities such as VPC Flow Logs and AWS CloudTrail are also available to audit network access, including allowed/denied requests and API calls, respectively.

Update management

To ensure the best results when you run Windows Server on Amazon EC2, we recommend that you implement the following best practices:

- Configure Windows Update
- Update drivers
- Use the latest Windows AMIs
- Test performance before migration
- Update launch agents
- Reboot your Windows instance after you install updates. For more information, see Reboot your Amazon EC2 instance.

For information about how to upgrade or migrate a Windows instance to a newer version of Windows Server, see Upgrade an EC2 Windows instance to a newer version of Windows Server.

Configure Windows Update

By default, instances that are launched from AWS Windows Server AMIs don't receive updates through Windows Update.

Update Windows drivers

Maintain the latest drivers on all Windows EC2 instances to ensure that the latest issue fixes and performance enhancements are applied across your fleet. Depending on your instance type, you should update the AWS PV, Amazon ENA, and AWS NVMe drivers.

- Use the AWS Systems Manager Automation runbook AWSSupport-UpgradeWindowsAWSDrivers to easily apply the updates across your instances.

Launch instances using the latest Windows AMIs

AWS releases new Windows AMIs each month, which contain the latest OS patches, drivers, and launch agents. You should leverage the latest AMI when you launch new instances or when you build your own custom images.

- To view updates to each release of the AWS Windows AMIs, see AWS Windows AMI version history.
- To build with the latest available AMIs, see Query for the Latest Windows AMI Using Systems Manager Parameter Store.
- For more information about specialized Windows AMIs that you can use to launch instances for your database and compliance hardening use cases, see Specialized Windows AMIs in the *AWS Windows AMI Reference*.

Test system/application performance before migration

Migrating enterprise applications to AWS can involve many variables and configurations. Always performance test the EC2 solution to ensure that:

- Instance types are properly configured, including instance size, enhanced networking, and tenancy (shared or dedicated).

- Instance topology is appropriate for the workload and leverages high-performance features when necessary, such as dedicated tenancy, placement groups, instance store volumes, and bare metal.

Install the latest version of EC2Launch v2

Install the latest EC2Launch v2 agent to ensure that the latest enhancements are applied across your fleet. For more information, see Install EC2Launch v2.

If you have a mixed fleet, or if you want to continue to use the EC2Launch (Windows Server 2016 and 2019) or EC2 Config (legacy OS only) agents, update to the latest versions of the respective agents.

Automatic updates are supported on the following combinations of Windows Server version and launch agents. You can opt in to automatic updates in the SSM Quick Setup Host Management console under **Amazon EC2 Launch Agents**.

Windows Version	EC2Launch v1	EC2Launch v2
2016	✓	✓
2019	✓	✓
2022		✓

- For more information about updating to EC2Launch v2, see the section called “Install EC2Launch v2”.
- For information to manually update EC2Config, see the section called “Install EC2Config”.
- For information to manually update EC2Launch, see the section called “Install EC2Launch”.

Configuration management

Amazon Machine Images (AMIs) provide an initial configuration for an Amazon EC2 instance, which includes the Windows OS and optional customer-specific customizations, such as applications and security controls. Create an AMI catalog containing customized security configuration baselines to ensure that all Windows instances are launched with standard security controls. Security

baselines can be baked into an AMI, bootstrapped dynamically when an EC2 instance is launched, or packaged as a product for uniform distribution through AWS Service Catalog portfolios. For more information on securing an AMI, see Best Practices for Building an AMI.

Each Amazon EC2 instance should adhere to organizational security standards. Do not install any Windows roles and features that are not required, and do install software to protect against malicious code (antivirus, antimalware, exploit mitigation), monitor host-integrity, and perform intrusion detection. Configure security software to monitor and maintain OS security settings, protect the integrity of critical OS files, and alert on deviations from the security baseline. Consider implementing recommended security configuration benchmarks published by Microsoft, the Center for Internet Security (CIS), or the National Institute of Standards and Technology (NIST). Consider using other Microsoft tools for particular application servers, such as the Best Practice Analyzer for SQL Server.

AWS customers can also run Amazon Inspector assessments to improve the security and compliance of applications deployed on Amazon EC2 instances. Amazon Inspector automatically assesses applications for vulnerabilities or deviations from best practices and includes a knowledge base of hundreds of rules mapped to common security compliance standards (for example, PCI DSS) and vulnerability definitions. Examples of built-in rules include checking if remote root login is enabled, or if vulnerable software versions are installed. These rules are regularly updated by AWS security researchers.

When securing Windows instances, we recommend that you implement Active Directory Domain Services to enable a scalable, secure, and manageable infrastructure for distributed locations. Additionally, after launching instances from the Amazon EC2 console or by using an Amazon EC2 provisioning tool, such as AWS CloudFormation, it is good practice to use native OS features, such as Microsoft Windows PowerShell DSC to maintain configuration state in the event that configuration drift occurs.

Change management

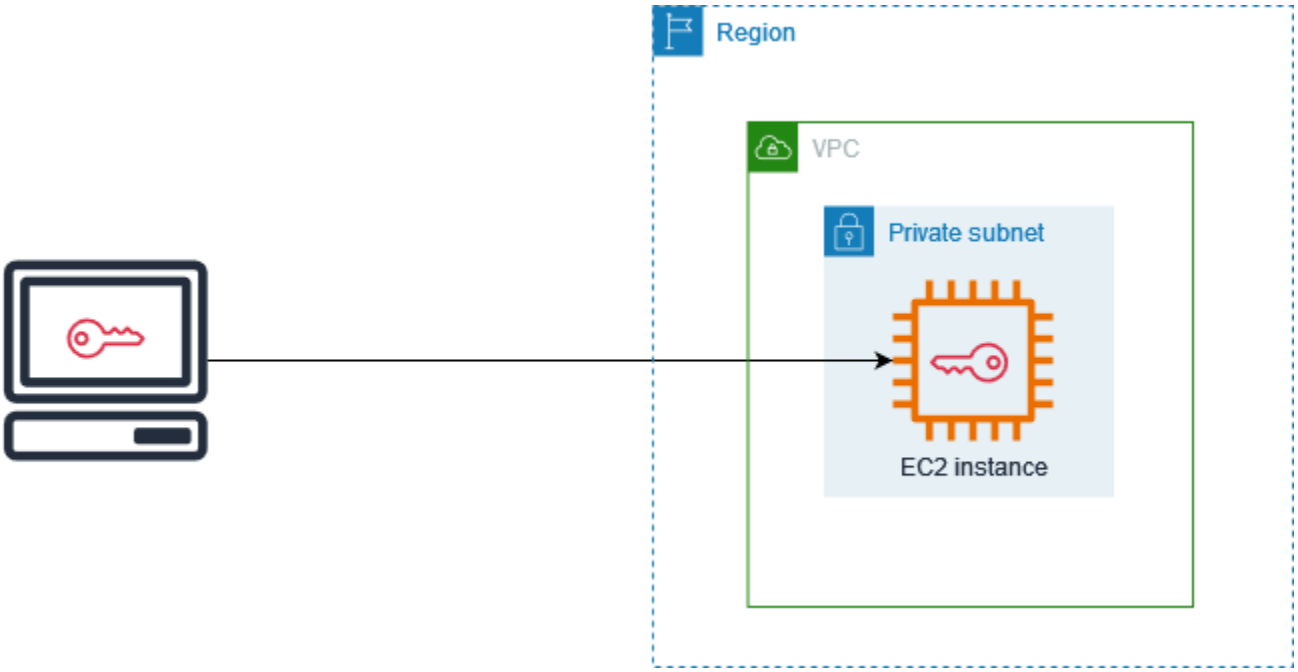
After initial security baselines are applied to Amazon EC2 instances at launch, control ongoing Amazon EC2 changes to maintain the security of your virtual machines. Establish a change management process to authorize and incorporate changes to AWS resources (such as security groups, route tables, and network ACLs) as well as to OS and application configurations (such as Windows or application patching, software upgrades, or configuration file updates).

AWS provides several tools to help manage changes to AWS resources, including AWS CloudTrail, AWS Config, CloudFormation, and AWS Elastic Beanstalk, and management packs for Systems

Center Operations Manager and System Center Virtual Machine Manager. Note that Microsoft releases Windows patches the second Tuesday of each month (or as needed) and AWS updates all Windows AMIs managed by AWS within five days after Microsoft releases a patch. Therefore it is important to continually patch all baseline AMIs, update CloudFormation templates and Auto Scaling group configurations with the latest AMI IDs, and implement tools to automate running instance patch management.

Microsoft provides several options for managing Windows OS and application changes. SCCM, for example, provides full lifecycle coverage of environment modifications. Select tools that address business requirements and control how changes will affect application SLAs, capacity, security, and disaster recovery procedures. Avoid manual changes and instead leverage automated configuration management software or command line tools such as the EC2 Run Command or Windows PowerShell to implement scripted, repeatable change processes. To assist with this requirement, use bastion hosts with enhanced logging for all interactions with your Windows instances to ensure that all events and tasks are automatically recorded.

Audit and accountability for Amazon EC2 Windows instances



AWS CloudTrail, AWS Config, and AWS Config Rules provide audit and change tracking features for auditing AWS resource changes. Configure Windows event logs to send local log files to a centralized log management system to preserve log data for security and operational behavior analysis. Microsoft System Center Operations Manager (SCOM) aggregates information about Microsoft applications deployed to Windows instances and applies preconfigured and custom rulesets based on application roles and services. System Center Management Packs build on SCOM to provide application-specific monitoring and configuration guidance. These Management Packs support Windows Server Active Directory, SharePoint Server 2013, Exchange Server 2013, Lync Server 2013, SQL Server 2014, and many more servers and technologies.

In addition to Microsoft systems management tools, customers can use Amazon CloudWatch to monitor instance CPU utilization, disk performance, network I/O, and perform host and instance status checks. The EC2Config, EC2Launch, and EC2Launch v2 launch agents provide access to additional, advanced features for Windows instances. For example, they can export Windows system, security, application, and Internet Information Services (IIS) logs to CloudWatch Logs which can then be integrated with Amazon CloudWatch metrics and alarms. Customers can also create scripts that export Windows performance counters to Amazon CloudWatch custom metrics.

Amazon EC2 key pairs and Amazon EC2 instances

A key pair, consisting of a public key and a private key, is a set of security credentials that you use to prove your identity when connecting to an Amazon EC2 instance. For Linux instances, the private key allows you to securely SSH into your instance. For Windows instances, the private key is required to decrypt the administrator password, which you then use to connect to your instance.

Amazon EC2 stores the public key on your instance, and you store the private key, as shown in the following diagram. It's important that you store your private key in a secure place because anyone who possesses your private key can connect to your instances that use the key pair.

When you launch an instance, you can specify a key pair, so that you can connect to your instance using a method that requires a key pair. Depending on how you manage your security, you can specify the same key pair for all your instances or you can specify different key pairs.

For Linux instances, when your instance boots for the first time, the public key that you specified at launch is placed on your Linux instance in an entry within `~/.ssh/authorized_keys`. When you connect to your Linux instance using SSH, to log in you must specify the private key that corresponds to the public key.

For more information about connecting to your EC2 instance, see Connect to your EC2 instance.

Important

Because Amazon EC2 doesn't keep a copy of your private key, there is no way to recover a private key if you lose it. However, there can still be a way to connect to instances for which you've lost the private key. For more information, see I've lost my private key. How can I connect to my instance?

As an alternative to key pairs, you can use AWS Systems Manager Session Manager to connect to your instance with an interactive browser-based shell or the AWS Command Line Interface (AWS CLI).

Contents

- Create a key pair for your Amazon EC2 instance
- Describe your key pairs
- Delete your key pair
- Add or replace a public key on your Linux instance
- Verify the fingerprint of your key pair

Create a key pair for your Amazon EC2 instance

You can use Amazon EC2 to create your key pairs, or you can use a third-party tool to create your key pairs, and then import them to Amazon EC2.

Amazon EC2 supports 2048-bit SSH-2 RSA keys for Linux and Windows instances. Amazon EC2 also supports ED25519 keys for Linux instances.

For instructions on how to connect to your instance after you have created a key pair, see the section called “Connect to your Linux instance using SSH” and the section called “Connect to your Windows instance using RDP”.

Contents

- Create a key pair using Amazon EC2
- Create a key pair using AWS CloudFormation
- Create a key pair using a third-party tool and import the public key to Amazon EC2

Create a key pair using Amazon EC2

When you create a key pair using Amazon EC2, the public key is stored in Amazon EC2, and you store the private key.

You can create up to 5,000 key pairs per Region. To request an increase, create a support case. For more information, see Creating a support case in the *Support User Guide*.

Console

To create a key pair using Amazon EC2

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, under **Network & Security**, choose **Key Pairs**.
3. Choose **Create key pair**.
4. For **Name**, enter a descriptive name for the key pair. Amazon EC2 associates the public key with the name that you specify as the key name. A key name can include up to 255 ASCII characters. It can't include leading or trailing spaces.
5. Select a key pair type appropriate for your operating system:

   (Linux instances) For **Key pair type**, choose either **RSA** or **ED25519**.

   (Windows instances) For **Key pair type**, choose **RSA**. **ED25519** keys are not supported for Windows instances.
6. For **Private key file format**, choose the format in which to save the private key. To save the private key in a format that can be used with OpenSSH, choose **pem**. To save the private key in a format that can be used with PuTTY, choose **ppk**.
7. To add a tag to the public key, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.
8. Choose **Create key pair**.
9. The private key file is automatically downloaded by your browser. The base file name is the name that you specified as the name of your key pair, and the file name extension is determined by the file format that you chose. Save the private key file in a safe place.

   > **Important**
   >
   > This is the only chance for you to save the private key file.

10. If you plan to use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

```
chmod 400 key-pair-name.pem
```

If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see Error: Unprotected private key file.

AWS CLI

To create a key pair using Amazon EC2

1. Use the create-key-pair command as follows to generate the key pair and to save the private key to a `.pem` file. The `--query` option prints the private key material to the output. The `--output` option saves the private key material in the specified file. The extension should be either `.pem` or `.ppk`, depending on the key format. The private key name can be different from the public key name, but for ease of use, use the same name.

```
aws ec2 create-key-pair \
    --key-name my-key-pair \
    --key-type rsa \
    --key-format pem \
    --query "KeyMaterial" \
    --output text > my-key-pair.pem
```

2. If you plan to use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

```
chmod 400 key-pair-name.pem
```

If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see Error: Unprotected private key file.

PowerShell

To create a key pair using Amazon EC2

Use the New-EC2KeyPair cmdlet as follows to generate the key and save it to a `.pem` or `.ppk` file. The **Out-File** cmdlet saves the private key material in a file with the specified extension. The extension should be either `.pem` or `.ppk`, depending on the key format. The private key name can be different from the public key name, but for ease of use, use the same name.

```
(New-EC2KeyPair `
    -KeyName "my-key-pair" `
    -KeyType "rsa" `
    -KeyFormat "pem").KeyMaterial | Out-File -Encoding ascii -FilePath C:\path\my-key-pair.pem
```

Create a key pair using AWS CloudFormation

When you create a new key pair using CloudFormation, the private key is saved to AWS Systems Manager Parameter Store. The parameter name has the following format:

```
/ec2/keypair/key_pair_id
```

For more information, see AWS Systems Manager Parameter Store in the *AWS Systems Manager User Guide*.

To create a key pair using CloudFormation

1. Specify the AWS::EC2::KeyPair resource in your template.

   ```
   Resources:
     NewKeyPair:
       Type: 'AWS::EC2::KeyPair'
       Properties:
         KeyName: new-key-pair
   ```

2. Use the describe-key-pairs command as follows to get the ID of the key pair.

   ```
   aws ec2 describe-key-pairs --filters Name=key-name,Values=new-key-pair --query
    KeyPairs[*].KeyPairId --output text
   ```

   The following is example output.

   ```
   key-05abb699beEXAMPLE
   ```

3. Use the get-parameter command as follows to get the parameter for your key and save the key material in a `.pem` file.

```
aws ssm get-parameter --name /ec2/keypair/key-05abb699beEXAMPLE --with-decryption
 --query Parameter.Value --output text > new-key-pair.pem
```

Required IAM permissions

To enable CloudFormation to manage Parameter Store parameters on your behalf, the IAM role assumed by CloudFormation or your user must have the following permissions:

- `ssm:PutParameter` – Grants permission to create a parameter for the private key material.
- `ssm:DeleteParameter` – Grants permission to delete the parameter that stored the private key material. This permission is required whether the key pair was imported or created by CloudFormation.

When CloudFormation deletes a key pair that was created or imported by a stack, it performs a permissions check to determine whether you have permission to delete parameters, even though CloudFormation creates a parameter only when it creates a key pair, not when it imports a key pair. CloudFormation tests for the required permission using a fabricated parameter name that does not match any parameter in your account. Therefore, you might see a fabricated parameter name in the `AccessDeniedException` error message.

Create a key pair using a third-party tool and import the public key to Amazon EC2

Instead of using Amazon EC2 to create a key pair, you can create an RSA or ED25519 key pair by using a third-party tool and then import the public key to Amazon EC2.

Requirements for key pairs

- Supported types:
  - (Linux and Windows) RSA
  - (Linux only) ED25519

> **Note**
>
> ED25519 keys are not supported for Windows instances.

  - Amazon EC2 does not accept DSA keys.
- Supported formats:
  - OpenSSH public key format (for Linux, the format in `~/.ssh/authorized_keys`)
  - (Linux only) If you connect using SSH while using the EC2 Instance Connect API, the SSH2 format is also supported.
  - SSH private key file format must be PEM or PPK
  - (RSA only) Base64 encoded DER format
  - (RSA only) SSH public key file format as specified in RFC 4716
- Supported lengths:
  - 1024, 2048, and 4096.
  - (Linux only) If you connect using SSH while using the EC2 Instance Connect API, the supported lengths are 2048 and 4096.

To create a key pair using a third-party tool

1. Generate a key pair with a third-party tool of your choice. For example, you can use **ssh-keygen** (a tool provided with the standard OpenSSH installation). Alternatively, Java, Ruby, Python, and many other programming languages provide standard libraries that you can use to create a key pair.

   > **Important**
   >
   > The private key must be in the PEM or PPK format. For example, use `ssh-keygen -m PEM` to generate the OpenSSH key in the PEM format.

2. Save the public key to a local file. For example, `~/.ssh/my-key-pair.pub` (Linux, macOS) or `C:\keys\my-key-pair.pub` (Windows). The file name extension for this file is not important.
3. Save the private key to a local file that has the `.pem` or `.ppk` extension. For example, `~/.ssh/my-key-pair.pem` or `~/.ssh/my-key-pair.ppk` (Linux, macOS) or `C:\keys\my-key-`

`pair.pem` or `C:\keys\my-key-pair.ppk` (Windows). The file extension is important because, depending on the tool you use to connect to your instance, you'll need a specific file format. OpenSSH requires a `.pem` file, while PuTTY requires a `.ppk` file.

> **Important**
>
> Save the private key file in a safe place. You'll need to provide the name of your public key when you launch an instance, and the corresponding private key each time you connect to the instance.

After you have created the key pair, use one of the following methods to import your public key to Amazon EC2.

Console

To import the public key to Amazon EC2

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Key Pairs**.
3. Choose **Import key pair**.
4. For **Name**, enter a descriptive name for the public key. The name can include up to 255 ASCII characters. It can't include leading or trailing spaces.

   > **Note**
   >
   > When you connect to your instance from the EC2 console, the console suggests this name for the name of your private key file.

5. Either choose **Browse** to navigate to and select your public key, or paste the contents of your public key into the **Public key contents** field.
6. Choose **Import key pair**.
7. Verify that the public key that you imported appears in the list of key pairs.

AWS CLI

To import the public key to Amazon EC2

Use the import-key-pair command.

```
aws ec2 import-key-pair \
    --key-name my-key-pair \
    --public-key-material fileb://path/my-key-pair.pub
```

To verify that the key pair was imported successfully

Use the describe-key-pairs command.

```
aws ec2 describe-key-pairs --key-names my-key-pair
```

PowerShell

To import the public key to Amazon EC2

Use the Import-EC2KeyPair cmdlet.

```
$publickey=[Io.File]::ReadAllText("C:\Users\TestUser\.ssh\id_rsa.pub")
Import-EC2KeyPair `
    -KeyName my-key-pair `
    -PublicKey $publickey
```

To verify that the key pair was imported successfully

Use the Get-EC2KeyPair cmdlet.

```
Get-EC2KeyPair -KeyName my-key-pair
```

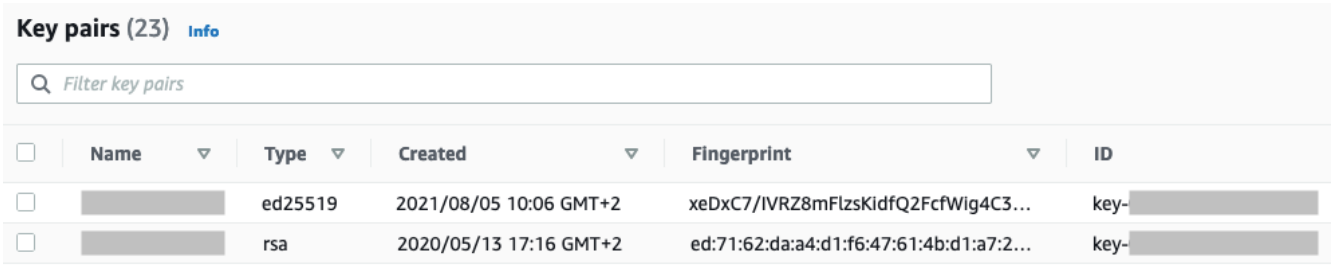
Describe your key pairs

You can describe the key pairs that you stored in Amazon EC2. You can also retrieve the public key material and identify the public key that was specified at launch.

Tasks

- Describe your key pairs
- Retrieve the public key material

- Identify the public key specified at launch



Describe your key pairs

You can view the following information about your public keys that are stored in Amazon EC2: public key name, ID, key type, fingerprint, public key material, the date and time (in the UTC time zone) the key was created by Amazon EC2 (if the key was created by a third-party tool, then it's the date and time the key was imported to Amazon EC2), and any tags that are associated with the public key.

Console

To view information about your key pairs

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the left navigator, choose **Key Pairs**.
3. You can view the information about each public key in the **Key pairs** table.

4. To view a public key's tags, select the checkbox next to the key, and then choose **Actions**, **Manage tags**.

AWS CLI

To view information about a key pair

Use the describe-key-pairs command.

```
aws ec2 describe-key-pairs --key-names key-pair-name
```

PowerShell

To view information about a key pair

Use the Get-EC2KeyPair cmdlet.

```
Get-EC2KeyPair -KeyName key-pair-name
```

Retrieve the public key material

You can get the public key material for your key pairs. The following is an example public key. Note that there are line breaks added for readability.

```
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS7O6V
hz2ItxCih+PnDSUaw+WNQn/mZphTk/a/gU8jEzoOWbkM4yxyb/wB96xbiFveSFJuOp/d6RJhJOI0iBXr
lsLnBItntckiJ7FbtxJMXLvvwJryDUilBMTjYtwB+QhYXUMOzce5Pjz5/i8SeJtjnV3iAoG/cQk+0FzZ
qaeJAAHco+CY/5WrUBkrHmFJr6HcXkvJdWPkYQS3xqC0+FmUZofz221CBt5IMucxXPkX4rWi+z7wB3Rb
BQoQzd8v7yeb7OzlPnWOyN0qFU0XA246RA8QFYiCNYwI3f05p6KLxEXAMPLE
```

Private key

To retrieve the public key material using ssh-keygen (Linux)

On your local Linux or macOS computer, use the **ssh-keygen** command. Specify the path where you downloaded your private key (the `.pem` file).

```
ssh-keygen -y -f /path_to_key_pair/my-key-pair.pem
```

If this **ssh-keygen** command fails, run the following **chmod** command to ensure that the private key file has the required permissions.

```
chmod 400 key-pair-name.pem
```

To retrieve the public key material using PuTTYgen (Windows)

On your local Windows computer, start PuTTYgen. Choose **Load**. Select the `.ppk` or `.pem` private key file. PuTTYgen displays the public key under **Public key for pasting into OpenSSH authorized_keys file**. You can also view the public key by choosing **Save public key**, specifying a name for the file, saving the file, and then opening the file.

AWS CLI

To retrieve the public key material

Use the following describe-key-pairs command and specify the `--include-public-key` option.

```
aws ec2 describe-key-pairs \
    --key-names key-pair-name \
    --include-public-key \
    --query "KeyPairs[].PublicKey"
```

PowerShell

To retrieve the public key material

Use the Get-EC2KeyPair cmdlet.

```
(Get-EC2KeyPair -KeyName key-pair-name -IncludePublicKey $true).PublicKey
```

IMDSv2

Linux

Run the following commands from your Linux instance.

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-
token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-
data/public-keys/0/openssh-key
```

Windows

Run the following cmdlets from your Windows instance.

```
[string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds"
 = "21600"} -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} -Method GET -Uri
 http://169.254.169.254/latest/meta-data/public-keys/0/openssh-key
```

IMDSv1

Linux

Run the following command from your Linux instance.

```
curl http://169.254.169.254/latest/meta-data/public-keys/0/openssh-key
```

Windows

Run the following cmdlet from your Windows instance.

```
Invoke-RestMethod -uri  http://169.254.169.254/latest/meta-data/public-keys/0/
openssh-key
```

Identify the public key specified at launch

If you specify a public key when you launch an instance, the public key name is recorded by the instance. The public key name reported for an instance does not change, even if you change the public key on the instance or add public keys.

Console

To identify the public key specified at instance launch

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Details** tab, under **Instance details**, find **Key pair assigned at launch**.

AWS CLI

To identify the public key specified at instance launch

Use the following describe-instances command.

```
aws ec2 describe-instances \
    --instance-id i-1234567890abcdef0 \
    --query "Reservations[].Instances[].KeyName" \
    --output text
```

The following is example output.

```
key-pair-name
```

PowerShell

To identify the public key specified at instance launch

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance -InstanceId i-1234567890abcdef0).Instances | Select KeyName
```

The following is example output.

```
KeyName
-------
key-pair-name
```

Delete your key pair

You can delete a key pair, which removes the public key that is stored in Amazon EC2. Deleting a key pair does not delete the matching private key.

When you delete a public key using the following methods, you're only deleting the public key that you stored in Amazon EC2 when you created or imported the key pair. Deleting a public key doesn't remove the public key from any instances to which you've added it, either when you launched the instance or later. It also doesn't delete the private key on your local computer. You can continue to connect to instances that you launched using a public key that you've deleted from Amazon EC2 as long as you still have the private key (`.pem`) file.

Important

If you're using an Auto Scaling group (for example, in an Elastic Beanstalk environment), ensure that the public key you're deleting is not specified in an associated launch template or launch configuration. If Amazon EC2 Auto Scaling detects an unhealthy instance, it launches a replacement instance. However, the instance launch fails if the public key cannot be found. For more information, see Launch templates in the *Amazon EC2 Auto Scaling User Guide*.

Console

To delete your public key on Amazon EC2

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Key Pairs**.
3. Select the key pair to delete and choose **Actions**, **Delete**.
4. In the confirmation field, enter `Delete` and then choose **Delete**.

AWS CLI

To delete your public key on Amazon EC2

Use the delete-key-pair command.

```
aws ec2 delete-key-pair --key-name my-key-pair
```

PowerShell

To delete your public key on Amazon EC2

Use the Remove-EC2KeyPair cmdlet.

```
Remove-EC2KeyPair -KeyName my-key-pair
```

Add or replace a public key on your Linux instance

Description
If you lose a private key, you lose access to any instances that use the key pair. For more information about connecting to an instance using a different key pair than the one that you specified at launch, see I've lost my private key.

When you launch an instance, you can specify a key pair. If you specify a key pair at launch, when your instance boots for the first time, the public key material is placed on your Linux instance in

an entry within ~/.ssh/authorized_keys. When you first connect to your Linux instance using SSH, you specify the default user and the private key that corresponds to the public key that is stored on your Linux instance.

After you connect to your instance, you can change the key pair that is used to access the default system account of your instance by adding a new public key on the instance, or by replacing the public key (deleting the existing public key and adding a new one) on the instance. You can also remove all public keys from an instance.

You might add or replace a key pair for the following reasons:

- If a user in your organization requires access to the system user using a separate key pair, you can add the public key to your instance.
- If someone has a copy of the private key (.pem file) and you want to prevent them from connecting to your instance (for example, if they've left your organization), you can delete the public key on the instance and replace it with a new one.
- If you create a Linux AMI from an instance, the public key material is copied from the instance to the AMI. If you launch an instance from the AMI, the new instance includes the public key from the original instance. To prevent someone who has the private key from connecting to the new instance, you can remove the public key from the original instance *before* creating the AMI.

Use the following procedures to modify the key pair for the default user, such as ec2-user. For information about adding users to your instance, see the documentation for the operating system on your instance.

To add or replace a key pair

1. Create a new key pair using the Amazon EC2 console or a third-party tool.
2. Retrieve the public key from your new key pair. For more information, see Retrieve the public key material.
3. Connect to your instance.
4. On the instance, using the text editor of your choice, open the .ssh/authorized_keys file. Paste the public key information from your new key pair underneath the existing public key information and then save the file.
5. Disconnect from your instance. Test that you can connect to your instance using the private key file from the new key pair.

6. If you're using Auto Scaling, EC2 fleet, or a launch template to launch your instances, check whether the key pair that you're replacing is specified in your launch template or launch configuration. Otherwise, instance launches will fail.
7. (Optional) If you're replacing an existing key pair, connect to your instance and delete the public key information for the original key pair from the `.ssh/authorized_keys` file.

To remove a public key from an instance

1. Connect to your instance.
2. Using a text editor of your choice, open the `.ssh/authorized_keys` file on the instance. Delete the public key information, and then save the file.

> **Warning**
>
> If you remove all the public keys from an instance and disconnect from the instance, you can't connect to the instance again unless you've configured an alternate way to log in.

Verify the fingerprint of your key pair

To verify the fingerprint of your key pair, compare the fingerprint displayed on the **Key pairs** page in the Amazon EC2 console, or returned by the describe-key-pairs command, with the fingerprint that you generate using the private key on your local computer. These fingerprints should match.

When Amazon EC2 calculates a fingerprint, Amazon EC2 might append padding to the fingerprint with = characters. Other tools, such as **ssh-keygen**, might omit this padding.

If you're trying to verify the fingerprint of your Linux EC2 instance, not the fingerprint of your key pair, see Get the instance fingerprint.

How the fingerprints are calculated

Amazon EC2 uses different hash functions to calculate the fingerprints for RSA and ED25519 key pairs. Furthermore, for RSA key pairs, Amazon EC2 calculates the fingerprints differently using different hash functions depending on whether the key pair was created by Amazon EC2 or imported to Amazon EC2.

The following table lists the hash functions that are used to calculate the fingerprints for RSA and ED25519 key pairs that are created by Amazon EC2 and imported to Amazon EC2.

(Linux instances) Hash functions used to calculate fingerprints

Key pair source	RSA key pairs (Windows and Linux)	ED25519 key pairs (Linux)
Created by Amazon EC2	SHA-1	SHA-256
Imported to Amazon EC2	MD5[1]	SHA-256

[1] If you import a public RSA key to Amazon EC2, the fingerprint is calculated using an MD5 hash function. This is true regardless of how you created the key pair, for example, by using a third-party tool or by generating a new public key from an existing private key created using Amazon EC2.

When using the same key pair in different Regions

If you plan to use the same key pair to connect to instances in different AWS Regions, you must import the public key to all of the Regions in which you'll use it. If you use Amazon EC2 to create the key pair, you can Retrieve the public key material so that you can import the public key to the other Regions.

Note

- If you create an RSA key pair using Amazon EC2, and then you generate a public key from the Amazon EC2 private key, the imported public keys will have a different fingerprint than the original public key. This is because the fingerprint of the original RSA key created using Amazon EC2 is calculated using a SHA-1 hash function, while the fingerprint of the imported RSA keys is calculated using an MD5 hash function.
- For ED25519 key pairs, the fingerprints will be same regardless of whether they're created by Amazon EC2 or imported to Amazon EC2, because the same SHA-256 hash function is used to calculate the fingerprint.

Generate a fingerprint from the private key

Use one of the following commands to generate a fingerprint from the private key on your local machine.

If you're using a Windows local machine, you can run the following commands using the Windows Subsystem for Linux (WSL). Install the WSL and a Linux distribution using the instructions in the How to install Linux on Windows with WSL. The example in the instructions installs the Ubuntu distribution of Linux, but you can install any distribution. You are prompted to restart your computer for the changes to take effect.

- **If you created the key pair using Amazon EC2**

  Use the OpenSSL tools to generate a fingerprint as shown in the following examples.

  For RSA key pairs:

  ```
  openssl pkcs8 -in path_to_private_key -inform PEM -outform DER -topk8 -nocrypt |
   openssl sha1 -c
  ```

  (Linux instances) For ED25519 key pairs:

  ```
  ssh-keygen -l -f path_to_private_key
  ```

- **(RSA key pairs only) If you imported the public key to Amazon EC2**

  You can follow this procedure regardless of how you created the key pair, for example, by using a third-party tool or by generating a new public key from an existing private key created using Amazon EC2

  Use the OpenSSL tools to generate the fingerprint as shown in the following example.

  ```
  openssl rsa -in path_to_private_key -pubout -outform DER | openssl md5 -c
  ```

- **If you created an OpenSSH key pair using OpenSSH 7.8 or later and imported the public key to Amazon EC2**

  Use **ssh-keygen** to generate the fingerprint as shown in the following examples.

  For RSA key pairs:

```
ssh-keygen -ef path_to_private_key -m PEM | openssl rsa -RSAPublicKey_in -outform DER
 | openssl md5 -c
```

(Linux instances) For ED25519 key pairs:

```
ssh-keygen -l -f path_to_private_key
```

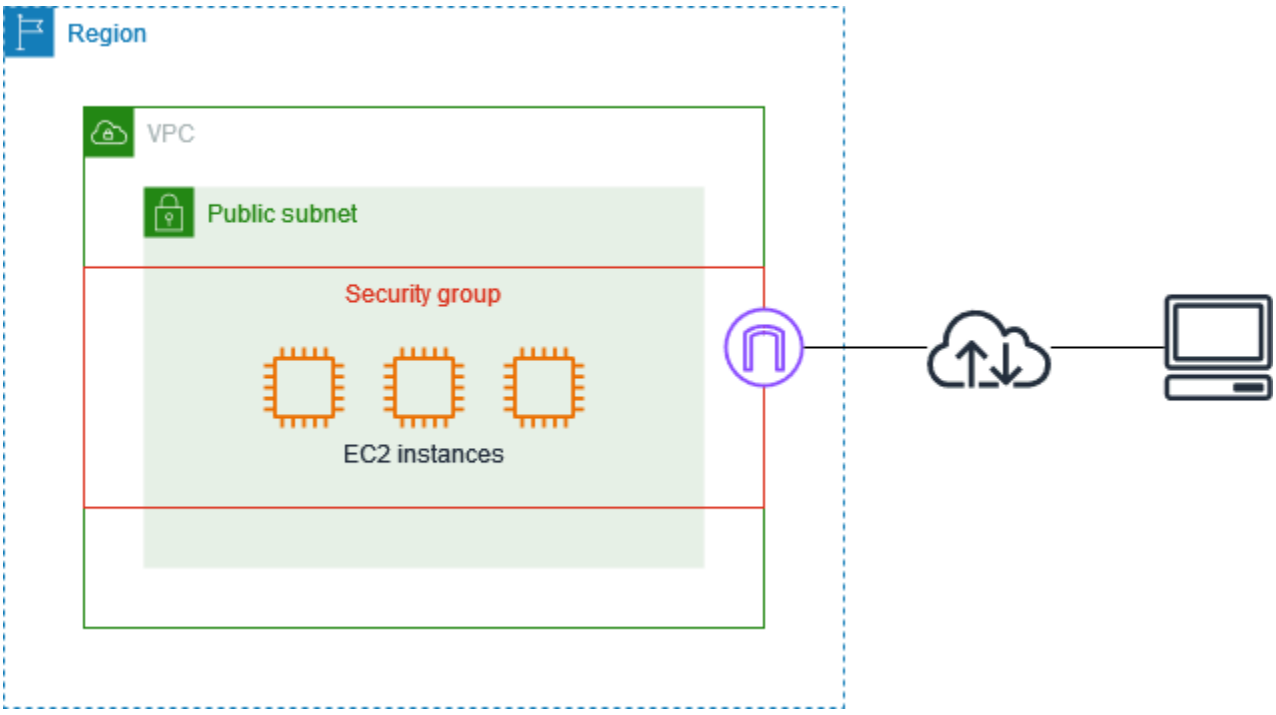
Amazon EC2 security groups for your EC2 instances

A *security group* acts as a virtual firewall for your EC2 instances to control incoming and outgoing traffic. Inbound rules control the incoming traffic to your instance, and outbound rules control the outgoing traffic from your instance. When you launch an instance, you can specify one or more security groups. If you don't specify a security group, Amazon EC2 uses the default security group for the VPC. After you launch an instance, you can change its security groups.

Security is a shared responsibility between AWS and you. For more information, see Security in Amazon EC2. AWS provides security groups as one of the tools for securing your instances, and you need to configure them to meet your security needs. If you have requirements that aren't fully met by security groups, you can maintain your own firewall on any of your instances in addition to using security groups.

Pricing

There is no additional charge for using security groups.



Contents

- Overview
- Create a security group for your Amazon EC2 instance
- Change the security groups for your Amazon EC2 instance
- Delete an Amazon EC2 security group
- Amazon EC2 security group connection tracking
- Security group rules for different use cases

Overview

You can associate each instance with multiple security groups, and you can associate each security group with multiple instances. You add rules to each security group that allow traffic to or from its associated instances. You can modify the rules for a security group at any time. New and modified rules are automatically applied to all instances that are associated with the security group. When Amazon EC2 decides whether to allow traffic to reach an instance, it evaluates all rules from all security groups that are associated with the instance. For more information, see Security group rules in the *Amazon VPC User Guide*.

The following diagram shows a VPC with a subnet, an internet gateway, and a security group. The subnet contains EC2 instances. The security group is associated with the instances. The only traffic that reaches the instance is the traffic allowed by the security group rules. For example, if the security group contains a rule that allows SSH traffic from your network, then you can connect to your instance from your computer using SSH. If the security group contains a rule that allows all traffic from the resources associated with it, then each instance can receive any traffic sent from the other instances.

Security groups are stateful—if you send a request from your instance, the response traffic for that request is allowed to flow in regardless of inbound security group rules. Also, responses to allowed inbound traffic are allowed to flow out, regardless of outbound rules. For more information, see Connection tracking.

Create a security group for your Amazon EC2 instance

Security groups act as a firewall for associated instances, controlling both inbound and outbound traffic at the instance level. You can add rules to a security group that enable you to connect to your instance using SSH (Linux instances) or RDP (Windows instances). You can also add rules that allow client traffic, for example, HTTP and HTTPS traffic destined to a web server.

You can associate a security group with an instance when you launch the instance. When you add or remove rules from associated security groups, those changes are automatically applied to all instances to which you've associated the security group.

After you launch an instance, you can associate additional security groups. For more information, see Change the security groups for your Amazon EC2 instance.

You can add inbound and outbound security group rules when you create a security group or you can add them later on. For more information, see Configure security group rules. For examples of rules that you can add to a security group, see Security group rules for different use cases.

Considerations

- New security groups start with only an outbound rule that allows all traffic to leave the resource. You must add rules to enable any inbound traffic or to restrict the outbound traffic.
- When configuring a source for a rule that allows SSH or RDP access to your instances, do not allow access from anywhere, because it would allow this access to your instance from all IP addresses on the internet. This is acceptable for a short time in a test environment, but it is unsafe for production environments.
- If there is more than one rule for a specific port, Amazon EC2 applies the most permissive rule. For example, if you have a rule that allows access to TCP port 22 (SSH) from IP address 203.0.113.1, and another rule that allows access to TCP port 22 from anywhere, then everyone has access to TCP port 22.
- You can associate multiple security groups with an instance. Therefore, an instance can have hundreds of rules that apply. This might cause problems when you access the instance. We recommend that you condense your rules as much as possible.
- When you specify a security group as the source or destination for a rule, the rule affects all instances that are associated with the security group. Incoming traffic is allowed based on the private IP addresses of the instances that are associated with the source security group (and not the public IP or Elastic IP addresses). For more information about IP addresses, see Amazon EC2 instance IP addressing.

- Amazon EC2 blocks traffic on port 25 by default. For more information, see Restriction on email sent using port 25.

Console

To create a security group

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Security Groups**.
3. Choose **Create security group**.
4. Enter a descriptive name and brief description for the security group. You can't change the name and description of a security group after it is created.
5. For **VPC**, choose the VPC in which you'll run your Amazon EC2 instances.
6. (Optional) To add inbound rules, choose **Inbound rules**. For each rule, choose **Add rule** and specify the protocol, port, and source. For example, to allow SSH traffic, choose **SSH** for **Type** and specify the public IPv4 address of your computer or network for **Source**.
7. (Optional) To add outbound rules, choose **Outbound rules**. For each rule, choose **Add rule** and specify the protocol, port, and destination. Otherwise, you can keep the default rule, which allows all outbound traffic.
8. (Optional) To add a tag, choose **Add new tag** and enter the tag key and value.
9. Choose **Create security group**.

AWS CLI

To create a security group

Use the following create-security-group command.

```
aws ec2 create-security-group \
    --group-name my-security-group \
    --description "my security group" \
    --vpc-id vpc-1234567890abcdef0
```

For examples that add rules, see the section called “Configure security group rules”.

PowerShell

To create a security group

Use the New-EC2SecurityGroup cmdlet.

```
New-EC2SecurityGroup `
    -GroupName my-security-group `
    -Description "my security group" `
    -VpcId vpc-1234567890abcdef0
```

For examples that add rules, see the section called “Configure security group rules”.

Change the security groups for your Amazon EC2 instance

You can specify security groups for your Amazon EC2 instances when you launch them. After you launch an instance, you can add or remove security groups. You can also add, remove, or edit security group rules for associated security groups at any time.

Security groups are associated with network interfaces. Adding or removing security groups changes the security groups associated with the primary network interface. You can also change the security groups associated with any secondary network interfaces. For more information, see Modify network interface attributes.

Tasks

- Add or remove security groups
- Configure security group rules

Add or remove security groups

After you launch an instance, you can add or remove security groups from the list of associated security groups. When you associate multiple security groups with an instance, the rules from each security group are effectively aggregated to create one set of rules. Amazon EC2 uses this set of rules to determine whether to allow traffic.

Requirements

- The instance must be in the `running` or `stopped` state.

Console

To change the security groups for an instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance, and then choose **Actions**, **Security**, **Change security groups**.
4. For **Associated security groups**, select a security group from the list and choose **Add security group**.

   To remove an already associated security group, choose **Remove** for that security group.
5. Choose **Save**.

AWS CLI

To change the security groups for an instance

Use the following modify-instance-attribute command.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --groups sg-1234567890abcdef0
```

PowerShell

To change the security groups for an instance

Use the Edit-EC2InstanceAttribute cmdlet.

```
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -Group sg-1234567890abcdef0
```

Configure security group rules

After you create a security group, you can add, update, and delete its security group rules. When you add, update, or delete a rule, the change is automatically applied to the resources that are associated with the security group.

For examples of rules that you can add to a security group, see Security group rules for different use cases.

Required permissions

Before you begin, ensure that you have the required permissions. For more information, see Example: Work with security groups.

Protocols and ports

- With the console, when you select a predefined type, **Protocol** and **Port range** are specified for you. To enter a port range, you must select one of the following custom types: **Custom TCP** or **Custom UDP**.
- With the AWS CLI, you can add a single rule with a single port using the `--protocol` and `--port` options. To add multiple rules, or a rule with a port range, use the `--ip-permissions` option instead.

Sources and destinations

- With the console, you can specify the following as sources for inbound rules or destinations for outbound rules:
  - **Custom** – An IPv4 CIDR block, an IPv6 CIDR block, a security group, or a prefix list.
  - **Anywhere-IPv4** – The 0.0.0.0/0 IPv4 CIDR block.
  - **Anywhere-IPv6** – The ::/0 IPv6 CIDR block.
  - **My IP** – The public IPv4 address of your local computer.
- With the AWS CLI, you can specify an IPv4 CIDR block using the `--cidr` option or a security group using the `--source-group` option. To specify a prefix list or an IPv6 CIDR block, use the `--ip-permissions` option.

> **Warning**
>
> If you add inbound rules for ports 22 (SSH) or 3389 (RDP), we strongly recommend that you authorize only the specific IP address or range of addresses that need access to your instances. If you choose **Anywhere-IPv4**, you allow traffic from all IPv4 addresses to access your instances using the specified protocol. If you choose **Anywhere-IPv6**, you allow traffic from all IPv6 addresses to access your instances using the specified protocol.

Console

To configure security group rules

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Security Groups**.
3. Select the security group.
4. To edit the inbound rules, choose **Edit inbound rules** from **Actions** or the **Inbound rules** tab.

   a. To add a rule, choose **Add rule** and enter the type, protocol, port, and source for the rule.

      If the type is TCP or UDP, you must enter the port range to allow. For custom ICMP, you must choose the ICMP type name from **Protocol**, and, if applicable, the code name from **Port range**. For any other type, the protocol and port range are configured for you.

   b. To update a rule, change its protocol, description, and source as needed. However, you can't change the source type. For example, if the source is an IPv4 CIDR block, you can't specify an IPv6 CIDR block, a prefix list, or a security group.

   c. To delete a rule, choose its **Delete** button.
5. To edit the outbound rules, choose **Edit outbound rules** from **Actions** or the **Outbound rules** tab.

   a. To add a rule, choose **Add rule** and enter the type, protocol, port, and destination for the rule. You can also enter an optional description.

      If the type is TCP or UDP, you must enter the port range to allow. For custom ICMP, you must choose the ICMP type name from **Protocol**, and, if applicable, the code name from **Port range**. For any other type, the protocol and port range are configured for you.

   b. To update a rule, change its protocol, description, and source as needed. However, you can't change the source type. For example, if the source is an IPv4 CIDR block, you can't specify an IPv6 CIDR block, a prefix list, or a security group.

   c. To delete a rule, choose its **Delete** button.
6. Choose **Save rules**.

AWS CLI

To add security group rules

Use the authorize-security-group-ingress command to add inbound rules. The following example allows inbound SSH traffic from the CIDR blocks in the specified prefix list.

```
aws ec2 authorize-security-group-ingress \
    --group-id sg-1234567890abcdef0 \
    --ip-permissions
 'IpProtocol=tcp,FromPort=22,ToPort=22,PrefixListIds=[{PrefixListId=pl-
f8a6439156EXAMPLE}]'
```

Use the authorize-security-group-egress command to add outbound rules. The following example allows outbound TCP traffic on port 80 to instances with the specified security group.

```
aws ec2 authorize-security-group-egress \
    --group-id sg-1234567890abcdef0 \
    --ip-permissions
 'IpProtocol=tcp,FromPort=80,ToPort=80,UserIdGroupPairs=[{GroupId=sg-0aad1c26bb6EXAMPLE}]'
```

To remove security group rules

Use the following revoke-security-group-ingress command to remove an inbound rule.

```
aws ec2 revoke-security-group-egress \
    --group id sg-1234567890abcdef0 \
    --security-group-rule-ids sgr-09ed298024EXAMPLE
```

Use the following revoke-security-group-egress command to remove an outbound rule.

```
aws ec2 revoke-security-group-ingress \
    --group id sg-1234567890abcdef0 \
    --security-group-rule-ids sgr-0352250c1aEXAMPLE
```

To modify security group rules

Use the modify-security-group-rules command. The following example changes the IPv4 CIDR block of the specified security group rule.

```
aws ec2 modify-security-group-rules \
    --group id sg-1234567890abcdef0 \
    --security-group-rules
 'SecurityGroupRuleId=sgr-09ed298024EXAMPLE,SecurityGroupRule={IpProtocol=tcp,FromPort=80,To
```

PowerShell

To add security group rules

Use the Grant-EC2SecurityGroupIngress cmdlet to add inbound rules. The following example allows inbound SSH traffic from the CIDR blocks in the specified prefix list.

```
$plid = New-Object -TypeName Amazon.EC2.Model.PrefixListId
$plid.Id = "pl-f8a6439156EXAMPLE"
Grant-EC2SecurityGroupIngress `
    -GroupId sg-1234567890abcdef0 `
    -IpPermission @{IpProtocol="tcp"; FromPort=22; ToPort=22; PrefixListIds=$plid}
```

Use the Grant-EC2SecurityGroupEgress cmdlet to add outbound rules. The following example allows outbound TCP traffic on port 80 to instances with the specified security group.

```
$uigp = New-Object -TypeName Amazon.EC2.Model.UserIdGroupPair
$uigp.GroupId = "sg-0aad1c26bb6EXAMPLE"
Grant-EC2SecurityGroupEgress `
    -GroupId sg-1234567890abcdef0 `
    -IpPermission @{IpProtocol="tcp"; FromPort=80; ToPort=80; UserIdGroupPairs=
$uigp}
```

To remove security group rules

Use the Revoke-EC2SecurityGroupIngress cmdlet to remove inbound rules.

```
Revoke-EC2SecurityGroupIngress `
    -GroupId sg-1234567890abcdef0 `
    -SecurityGroupRuleId sgr-09ed298024EXAMPLE
```

Use the Revoke-EC2SecurityGroupEgress cmdlet to remove outbound rules.

```
Revoke-EC2SecurityGroupEgress `
    -GroupId sg-1234567890abcdef0 `
```

```
    -SecurityGroupRuleId sgr-0352250c1aEXAMPLE
```

To modify security group rules

Use the Edit-EC2SecurityGroupRule cmdlet. The following example changes the IPv4 CIDR block of the specified security group rule.

```
$sgrr = New-Object -TypeName Amazon.EC2.Model.SecurityGroupRuleRequest
$sgrr.IpProtocol = "tcp"
$sgrr.FromPort = 80
$sgrr.ToPort = 80
$sgrr.CidrIpv4 = "0.0.0.0/0"
$sgr = New-Object -TypeName Amazon.EC2.Model.SecurityGroupRuleUpdate
$sgr.SecurityGroupRuleId = "sgr-09ed298024EXAMPLE"
$sgr.SecurityGroupRule = $sgrr
Edit-EC2SecurityGroupRule  `
    -GroupId sg-1234567890abcdef0 `
    -SecurityGroupRule $sgr
```

Delete an Amazon EC2 security group

When you are finished with a security group that you created for use with your Amazon EC2 instances, you can delete it.

Requirements

- The security group can't be associated with an instance or network interface.
- The security group can't be referenced by a rule in another security group.

Console

To delete a security group

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. (Optional) To verify that your security group is not associated with an instance, do the following:
   a. In the navigation pane, choose **Security Groups**.
   b. Copy the ID of the security group to delete.

c. In the navigation pane, choose **Instances**.

d. In the search bar, add **Security group IDs equals** filter and paste the ID of the security group. If there are no results, then the security group is not associated with an instance. Otherwise, you must disassociate the security group before you can delete it.

3. In the navigation pane, choose **Security Groups**.
4. Select the security group and choose **Actions**, **Delete security groups**.
5. If you selected more than one security group, you are prompted for confirmation. If some of the security groups can't be deleted, we display the status of each security group, which indicates whether it will be deleted. To confirm deletion, enter **Delete**.
6. Choose **Delete**.

AWS CLI

To delete a security group

Use the following delete-security-group command.

```
aws ec2 delete-security-group --group-id sg-1234567890abcdef0
```

PowerShell

To delete a security group

Use the Remove-EC2SecurityGroup cmdlet.

```
Remove-EC2SecurityGroup -GroupId sg-1234567890abcdef0
```

Amazon EC2 security group connection tracking

Your security groups use connection tracking to track information about traffic to and from the instance. Rules are applied based on the connection state of the traffic to determine if the traffic is allowed or denied. With this approach, security groups are stateful. This means that responses to inbound traffic are allowed to flow out of the instance regardless of outbound security group rules, and vice versa.

As an example, suppose that you initiate a command such as netcat or similar to your instances from your home computer, and your inbound security group rules allow ICMP traffic. Information

about the connection (including the port information) is tracked. Response traffic from the instance for the command is not tracked as a new request, but rather as an established connection, and is allowed to flow out of the instance, even if your outbound security group rules restrict outbound ICMP traffic.

For protocols other than TCP, UDP, or ICMP, only the IP address and protocol number is tracked. If your instance sends traffic to another host, and the host sends the same type of traffic to your instance within 600 seconds, the security group for your instance accepts it regardless of inbound security group rules. The security group accepts it because it's regarded as response traffic for the original traffic.

When you change a security group rule, its tracked connections are not immediately interrupted. The security group continues to allow packets until existing connections time out. To ensure that traffic is immediately interrupted, or that all traffic is subject to firewall rules regardless of the tracking state, you can use a network ACL for your subnet. Network ACLs are stateless and therefore do not automatically allow response traffic. Adding a network ACL that blocks traffic in either direction breaks existing connections. For more information, see Network ACLs in the *Amazon VPC User Guide*.

Note

Security groups have no effect on DNS traffic to or from the Route 53 Resolver, sometimes referred to as the 'VPC+2 IP address' (see What is Amazon Route 53 Resolver? in the *Amazon Route 53 Developer Guide*), or the 'AmazonProvidedDNS' (see Work with DHCP option sets in the *Amazon Virtual Private Cloud User Guide*). If you wish to filter DNS requests through the Route 53 Resolver, you can enable Route 53 Resolver DNS Firewall (see Route 53 Resolver DNS Firewall in the *Amazon Route 53 Developer Guide*).

Untracked connections

Not all flows of traffic are tracked. If a security group rule permits TCP or UDP flows for all traffic (0.0.0.0/0 or ::/0) and there is a corresponding rule in the other direction that permits all response traffic (0.0.0.0/0 or ::/0) for any port (0-65535), then that flow of traffic is not tracked, unless it is part of an automatically tracked connection. The response traffic for an untracked flow is allowed based on the inbound or outbound rule that permits the response traffic, not based on tracking information.

An untracked flow of traffic is immediately interrupted if the rule that enables the flow is removed or modified. For example, if you have an open (0.0.0.0/0) outbound rule, and you remove a rule that allows all (0.0.0.0/0) inbound SSH (TCP port 22) traffic to the instance (or modify it such that the connection would no longer be permitted), your existing SSH connections to the instance are immediately dropped. The connection was not previously being tracked, so the change will break the connection. On the other hand, if you have a narrower inbound rule that initially allows an SSH connection (meaning that the connection was tracked), but change that rule to no longer allow new connections from the address of the current SSH client, the existing SSH connection is not interrupted because it is tracked.

Automatically tracked connections

Connections made through the following are automatically tracked, even if the security group configuration does not otherwise require tracking:

- Egress-only internet gateways
- Global Accelerator accelerators
- NAT gateways
- Network Firewall firewall endpoints
- Network Load Balancers
- AWS PrivateLink (interface VPC endpoints)
- AWS Lambda (Hyperplane elastic network interfaces)
- DynamoDB gateway endpoints – Each connection to DynamoDB consumes 2 conntrack entries.

Connection tracking allowances

Amazon EC2 defines the maximum number of connections that can be tracked per instance. After the maximum is reached, any packets that are sent or received are dropped because a new connection cannot be established. When this happens, applications that send and receive packets cannot communicate properly. Use the `conntrack_allowance_available` network performance metric to determine the number of tracked connections still available for that instance type.

To determine whether packets were dropped because the network traffic for your instance exceeded the maximum number of connections that can be tracked, use the `conntrack_allowance_exceeded` network performance metric. For more information, see Monitor network performance for ENA settings on your EC2 instance.

With Elastic Load Balancing, if you exceed the maximum number of connections that can be tracked per instance, we recommend that you scale either the number of instances registered with the load balancer or the size of the instances registered with the load balancer.

Connection tracking best practices

Asymmetric routing, where traffic comes into an instance through one network interface and leaves through a different network interface, can reduce the peak performance that an instance can achieve if flows are tracked.

To maintain peak performance and optimize connection management when connection tracking is enabled for your security groups, we recommend the following configuration:

- Avoid asymmetric routing topologies, if possible.
- Instead of using security groups for filtering, use network ACLs.
- If you must use security groups with connection tracking, configure the shortest idle connection tracking timeout possible. For more details on idle connection tracking timeout, see the following section.
- With the shorter default timeouts on Nitrov6 instances, applications with long-lived connections (such as database connection pools, persistent HTTP connections, or streaming workloads) should configure an appropriate `TcpEstablishedTimeout` value at instance launch.
- For long-lived connections, configure TCP keep alives to be sent at intervals of less than 5 minutes to ensure connections stay open and maintain their tracked state. This helps prevent connections from being dropped due to idle timeout and reduces the overhead of connection re-establishment.

For more information about performance tuning on the Nitro system, see Nitro system considerations for performance tuning.

Idle connection tracking timeout

The security group tracks each connection established to ensure that return packets are delivered as expected. There is a maximum number of connections that can be tracked per instance. Connections that remain idle can lead to connection tracking exhaustion and cause connections not to be tracked and packets to be dropped. You can set the timeout for idle connection tracking on an Elastic network interface.

> **Note**
>
> This feature is available only with Nitro-based instances. You should test your applications on Nitrov6 generation instances with the reduced 350 second default connection tracking timeout before deploying to production.

There are three configurable timeouts:

- **TCP established timeout**: Timeout (in seconds) for idle TCP connections in an established state.
  - Min: 60 seconds
  - Max: 432000 seconds
  - Default: 350 seconds for Nitro v6 instance types (excluding P6e-GB200); 432000 seconds for all other instance types (including P6e-GB200).
  - Recommended: Less than 432000 seconds
- **UDP timeout**: Timeout (in seconds) for idle UDP flows that have seen traffic only in a single direction or a single request-response transaction.
  - Min: 30 seconds
  - Max: 60 seconds
  - Default: 30 seconds
- **UDP stream timeout**: Timeout (in seconds) for idle UDP flows classified as streams which have seen more than one request-response transaction.
  - Min: 60 seconds
  - Max: 180 seconds
  - Default: 180 seconds

You may want to modify the default timeouts for any of the following cases:

- If you are monitoring tracked connections using Amazon EC2 network performance metrics, the *conntrack_allowance_exceeded* and *conntrack_allowance_available* metrics enable you to monitor dropped packets and tracked connection utilization to proactively manage EC2 instance capacity with scale up or out actions to help meet network connections demand before dropping packets. If you are observing *conntrack_allowance_exceeded* drops on your EC2 instances, you may benefit

from setting a lower TCP established timeout to account for stale TCP/UDP sessions resulting from improper clients or network middle boxes.

- Typically, load balancers or firewalls have TCP Established idle timeout in the range of 60 to 90 minutes. If you are running workloads that are expected to handle a very high number of connections (greater than 100k) from appliances like network firewalls, configuring a similar timeout on an EC2 network interface is advised.
- If you are running a workload that uses an asymmetric routing topology, we recommend that you configure a TCP Established idle timeout of 60 seconds.
- If you are running workloads with high numbers of connections like DNS, SIP, SNMP, Syslog, Radius and other services that primarily use UDP to serve requests, setting the 'UDP-stream' timeout to 60s provides higher scale/performance for existing capacity and to prevent gray failures.
- For TCP/UDP connections through Network Load Balancers, all connections are tracked. Idle timeout value for TCP flows is 350secs and UDP flows is 120 secs, and varies from interface level timeout values. You may want to configure timeouts at the network interface level to allow for more flexibility for timeout than the defaults for the load balancer.

You have the option to configure the connection tracking timeouts when you do the following:

- Create a network interface
- Modify network interface attributes
- Launch an EC2 instance
- Create an EC2 instance launch template

Example

In the following example, the security group has inbound rules that allow TCP and ICMP traffic, and outbound rules that allow all outbound traffic.

Inbound

Protocol type	Port number	Source
TCP	22 (SSH)	203.0.113.1/32
TCP	80 (HTTP)	0.0.0.0/0

Protocol type	Port number	Source
TCP	80 (HTTP)	::/0
ICMP	All	0.0.0.0/0

Outbound

Protocol type	Port number	Destination
All	All	0.0.0.0/0
All	All	::/0

With a direct network connection to the instance or network interface, the tracking behavior is as follows:

- Inbound and outbound TCP traffic on port 22 (SSH) is tracked, because the inbound rule allows traffic from 203.0.113.1/32 only, and not all IP addresses (0.0.0.0/0).
- Inbound and outbound TCP traffic on port 80 (HTTP) is not tracked, because the inbound and outbound rules allow traffic from all IP addresses.
- ICMP traffic is always tracked.

If you remove the outbound rule for IPv4 traffic, all inbound and outbound IPv4 traffic is tracked, including traffic on port 80 (HTTP). The same applies for IPv6 traffic if you remove the outbound rule for IPv6 traffic.

Security group rules for different use cases

You can create a security group and add rules that reflect the role of the instance that's associated with the security group. For example, an instance that's configured as a web server needs security group rules that allow inbound HTTP and HTTPS access. Likewise, a database instance needs rules that allow access for the type of database, such as access over port 3306 for MySQL.

The following are examples of the kinds of rules that you can add to security groups for specific kinds of access.

Examples

- Web server rules
- Database server rules
- Rules to connect to instances from your computer
- Rules to connect to instances from an instance with the same security group
- Rules for ping/ICMP
- DNS server rules
- Amazon EFS rules
- Elastic Load Balancing rules

For instructions, see Create a security group and the section called "Configure security group rules".

Web server rules

The following inbound rules allow HTTP and HTTPS access from any IP address. If your VPC is enabled for IPv6, you can add rules to control inbound HTTP and HTTPS traffic from IPv6 addresses.

Protocol type	Protocol number	Port	Source IP	Notes
TCP	6	80 (HTTP)	0.0.0.0/0	Allows inbound HTTP access from any IPv4 address
TCP	6	443 (HTTPS)	0.0.0.0/0	Allows inbound HTTPS access from any IPv4 address
TCP	6	80 (HTTP)	::/0	Allows inbound HTTP access from any IPv6 address
TCP	6	443 (HTTPS)	::/0	Allows inbound HTTPS access from any IPv6 address

Database server rules

The following inbound rules are examples of rules you might add for database access, depending on what type of database you're running on your instance. For more information about Amazon RDS instances, see the Amazon RDS User Guide.

For the source IP, specify one of the following:

- A specific IP address or range of IP addresses (in CIDR block notation) in your local network
- A security group ID for a group of instances that access the database

Protocol type	Protocol number	Port	Notes
TCP	6	1433 (MS SQL)	The default port to access a Microsoft SQL Server database, for example, on an Amazon RDS instance
TCP	6	3306 (MYSQL/Aurora)	The default port to access a MySQL or Aurora database, for example, on an Amazon RDS instance
TCP	6	5439 (Redshift)	The default port to access an Amazon Redshift cluster database.
TCP	6	5432 (PostgreSQL)	The default port to access a PostgreSQL database, for example, on an Amazon RDS instance
TCP	6	1521 (Oracle)	The default port to access an Oracle database, for example, on an Amazon RDS instance

You can optionally restrict outbound traffic from your database servers. For example, you might want to allow access to the internet for software updates, but restrict all other kinds of traffic. You must first remove the default outbound rule that allows all outbound traffic.

Protocol type	Protocol number	Port	Destination IP	Notes
TCP	6	80 (HTTP)	0.0.0.0/0	Allows outbound HTTP access to any IPv4 address
TCP	6	443 (HTTPS)	0.0.0.0/0	Allows outbound HTTPS access to any IPv4 address
TCP	6	80 (HTTP)	::/0	(IPv6-enabled VPC only) Allows outbound HTTP access to any IPv6 address
TCP	6	443 (HTTPS)	::/0	(IPv6-enabled VPC only) Allows outbound HTTPS access to any IPv6 address

Rules to connect to instances from your computer

To connect to your instance, your security group must have inbound rules that allow SSH access (for Linux instances) or RDP access (for Windows instances).

Protocol type	Protocol number	Port	Source IP
TCP	6	22 (SSH)	The public IPv4 address of your computer, or a range of IP addresses in your local network. If your VPC is enabled for IPv6 and your instance has an IPv6 address, you can enter an IPv6 address or range.
TCP	6	3389 (RDP)	The public IPv4 address of your computer, or a range of IP addresses in your local network. If your VPC is enabled for IPv6 and your instance

Protocol type	Protocol number	Port	Source IP
			has an IPv6 address, you can enter an IPv6 address or range.

Rules to connect to instances from an instance with the same security group

To allow instances that are associated with the same security group to communicate with each other, you must explicitly add rules for this.

> **Note**
>
> If you configure routes to forward the traffic between two instances in different subnets through a middlebox appliance, you must ensure that the security groups for both instances allow traffic to flow between the instances. The security group for each instance must reference the private IP address of the other instance, or the CIDR range of the subnet that contains the other instance, as the source. If you reference the security group of the other instance as the source, this does not allow traffic to flow between the instances.

The following table describes the inbound rule for a security group that enables associated instances to communicate with each other. The rule allows all types of traffic.

Protocol type	Protocol number	Ports	Source IP
-1 (All)	-1 (All)	-1 (All)	The ID of the security group, or the CIDR range of the subnet that contains the other instance (see note).

Rules for ping/ICMP

The **ping** command is a type of ICMP traffic. To ping your instance, you must add one of the following inbound ICMP rules.

Type	Protocol	Source		
Custom ICMP - IPv4	Echo request	The public IPv4 address of your computer, a specific IPv4 address, or an IPv4 or IPv6 address from anywhere.		
All ICMP - IPv4	IPv4 ICMP (1)	The public IPv4 address of your computer, a specific IPv4 address, or an IPv4 or IPv6 address from anywhere.		

To use the **ping6** command to ping the IPv6 address for your instance, you must add the following inbound ICMPv6 rule.

Type	Protocol	Source		
All ICMP - IPv6	IPv6 ICMP (58)	The IPv6 address of your computer, a specific IPv4 address, or an IPv4 or IPv6 address from anywhere.		

DNS server rules

If you've set up your EC2 instance as a DNS server, you must ensure that TCP and UDP traffic can reach your DNS server over port 53.

For the source IP, specify one of the following:

- An IP address or range of IP addresses (in CIDR block notation) in a network
- The ID of a security group for the set of instances in your network that require access to the DNS server

Protocol type	Protocol number	Port
TCP	6	53
UDP	17	53

Amazon EFS rules

If you're using an Amazon EFS file system with your Amazon EC2 instances, the security group that you associate with your Amazon EFS mount targets must allow traffic over the NFS protocol.

Protocol type	Protocol number	Ports	Source IP	Notes
TCP	6	2049 (NFS)	The ID of the security group	Allows inbound NFS access from resources (including the mount target) associated with this security group

To mount an Amazon EFS file system on your Amazon EC2 instance, you must connect to your instance. Therefore, the security group associated with your instance must have rules that allow inbound SSH from your local computer or local network.

Protocol type	Protocol number	Ports	Source IP	Notes
TCP	6	22 (SSH)	The IP address range of your local computer, or the range of IP addresses (in CIDR block notation) for your network.	Allows inbound SSH access from your local computer.

Elastic Load Balancing rules

If you register your EC2 instances with a load balancer, the security group associated with your load balancer must allow communication with the instances. For more information, see the following in the Elastic Load Balancing documentation.

- Security groups for your Application Load Balancer
- Security groups for your Network Load Balancer
- Configure security groups for your Classic Load Balancer

NitroTPM for Amazon EC2 instances

Nitro Trusted Platform Module (NitroTPM) is a virtual device that is provided by the AWS Nitro System and conforms to the TPM 2.0 specification. It securely stores artifacts (such as passwords, certificates, or encryption keys) that are used to authenticate the instance. NitroTPM can generate keys and use them for cryptographic functions (such as hashing, signing, encryption, and decryption).

NitroTPM provides *measured boot*, a process where the bootloader and operating system create cryptographic hashes of every boot binary and combine them with the previous values in NitroTPM internal Platform Configuration Registers (PCRs). With measured boot, you can obtain signed PCR values from NitroTPM and use them to prove to remote entities the integrity of the instance's boot software. This is known as remote *attestation*.

With NitroTPM, keys and secrets can be tagged with a specific PCR value so that they can never be accessed if the value of the PCR, and thus the instance integrity, changes. This special form

of conditional access is referred to as *sealing and unsealing*. Operating system technologies, like BitLocker, can use NitroTPM to seal a drive decryption key so that the drive can only be decrypted when the operating system has booted correctly and is in a known good state.

To use NitroTPM, you must select an Amazon Machine Image (AMI) that has been configured for NitroTPM support, and then use the AMI to launch Nitro-based instances. You can select one of Amazon's prebuilt AMIs or create one yourself.

Pricing

There is no additional cost for using NitroTPM. You pay only for the underlying resources that you use.

Contents

- Requirements for using NitroTPM with Amazon EC2 instances

- Verify that an AMI is enabled for NitroTPM
- Enable or stop using NitroTPM on an Amazon EC2 instance
- Verify that an Amazon EC2 instance is enabled for NitroTPM
- Retrieve the public endorsement key for an EC2 instance

Requirements for using NitroTPM with Amazon EC2 instances

To launch an instance with NitroTPM enabled, you must meet the following requirements.

Topics

- AMIs
- Instance types
- Considerations

AMIs

The AMI must have NitroTPM enabled.

Linux AMIs

There are no preconfigured AMIs. You must configure your own AMI. For more information, see Enable a Linux AMI for NitroTPM.

Windows AMIs

To find an AWS Windows AMI that's preconfigured for NitroTPM and UEFI Secure Boot with Microsoft keys, see Find Windows Server AMIs configured with NitroTPM and UEFI Secure Boot in the *AWS Windows AMIs Reference*.

> **Note**
>
> **Operating system** — The AMI must include an operating system with a TPM 2.0 Command Response Buffer (CRB) driver. Most current operating systems include a TPM 2.0 CRB driver.
> **UEFI boot mode** — The AMI must be configured for UEFI boot mode. For more information, see UEFI Secure Boot for Amazon EC2 instances.

Instance types

You must use one of the following virtualized instance types:

- **General purpose**: M5, M5a, M5ad, M5d, M5dn, M5n, M5zn, M6a, M6g, M6gd, M6i, M6id, M6idn, M6in, M7a, M7g, M7gd, M7i, M7i-flex, M8a, M8azn, M8g, M8gb, M8gd, M8gn, M8i, M8id, M8i-flex, M8in, M8idn, M8ine, M8ib, M8idb, M9g, M9gd, T3, T3a, T4g, T8i
- **Compute optimized**: C5, C5a, C5ad, C5d, C5n, C6a, C6g, C6gd, C6gn, C6i, C6id, C6in, C7a, C7g, C7gd, C7gn, C7i, C7i-flex, C8a, C8g, C8gb, C8gd, C8gn, C8i, C8id, C8i-flex, C8in, C8ine, C8ib, C9g, C9gd
- **Memory optimized**: R5, R5a, R5ad, R5b, R5d, R5dn, R5n, R6a, R6g, R6gd, R6i, R6id, R6idn, R6in, R7a, R7g, R7gd, R7i, R7iz, R8a, R8g, R8gb, R8gd, R8gn, R8i, R8id, R8i-flex, R8in, R8idn, R8ib, R8idb, R9g, R9gd, U7i-6tb, U7i-8tb, U7i-12tb, U7in-16tb, U7in-24tb, U7in-32tb, X2idn, X2iedn, X2iezn, X8g, X8aedz, X8i, z1d
- **Storage optimized**: D3, D3en, I3en, I4i, I7i, I7ie, I8g, I8ge, Im4gn
- **Accelerated computing**: F2, G4dn, G5, G6, G6e, G6f, Gr6, Gr6f, G7, G7e, Inf1, Inf2, P5, P5e, P5en, P6-B200, P6-B300, P6e-GB200, Trn2, Trn2u
- **High-performance computing**: Hpc6a, Hpc6id, Hpc8a

Considerations

The following considerations apply when using NitroTPM:

- After you launch an instance using an AMI with NitroTPM enabled, if you want to change the instance type, the new instance type that you choose must also support NitroTPM.
- BitLocker volumes that are encrypted with NitroTPM-based keys can only be used on the original instance.
- The NitroTPM state is not displayed in the Amazon EC2 console.
- The NitroTPM state is not included in Amazon EBS snapshots.
- The NitroTPM state is not included in VM Import/Export images.
- NitroTPM is not supported on AWS Outposts., Local Zones, or Wavelength Zones.

Enable a Linux AMI for NitroTPM

To enable NitroTPM for an instance, you must launch the instance using an AMI with NitroTPM enabled. You must configure your Linux AMI with NitroTPM support when you register it. You can't configure NitroTPM support later on.

For the list of Windows AMIs that are preconfigured for NitroTPM support, see Requirements for using NitroTPM with Amazon EC2 instances.

You must create an AMI with NitroTPM configured by using the RegisterImage API. You can't use the Amazon EC2 console or VM Import/Export.

To enable a Linux AMI for NitroTPM

1. Launch a temporary instance with your required Linux AMI. Note the ID of its root volume, which you can find in the console on the **Storage** tab for the instance.
2. After the instance reaches the `running` state, create a snapshot of the instance's root volume. For more information, see Create a snapshot of an EBS volume.
3. Register the snapshot you created as an AMI. In the block device mapping, specify the snapshot that you created for the root volume.

   The following is an example register-image command. For `--tpm-support`, specify `v2.0`. For `--boot-mode`, specify `uefi`.

   ```
   aws ec2 register-image \
   ```

```
    --name my-image \
    --boot-mode uefi \
    --architecture x86_64 \
    --root-device-name /dev/xvda \
    --block-device-mappings DeviceName=/dev/
xvda,Ebs={SnapshotId=snap-0abcdef1234567890} \
    --tpm-support v2.0
```

The following is an example for the Register-EC2Image cmdlet.

```
$block = @{SnapshotId=snap-0abcdef1234567890}
Register-EC2Image `
    -Name my-image `
    -Architecture "x86_64" `
    -RootDeviceName /dev/xvda `
    -BlockDeviceMapping @{DeviceName="/dev/xvda";Ebs=$block} `
    -BootMode Uefi `
    -TpmSupport V20
```

4. Terminate the temporary instance that you launched in step 1.

Verify that an AMI is enabled for NitroTPM

To enable NitroTPM for an instance, you must launch the instance using an AMI with NitroTPM enabled. You can describe an image to verify that it is enabled for NitroTPM. If you are the AMI owner, you can describe the `tpmSupport` image attribute.

The Amazon EC2 console does not display `TpmSupport`.

AWS CLI

To verify that NitroTPM is enabled

Use the describe-images command.

```
aws ec2 describe-images \
    --image-ids ami-0abcdef1234567890 \
    --query Images[*].TpmSupport
```

If NitroTPM is enabled for the AMI, the output is as follows. If TPM is not enabled, the output is empty.

```
[
    "v2.0"
]
```

Alternatively, if you are the AMI owner, you can use the describe-image-attribute command with the `tpmSupport` attribute.

```
aws ec2 describe-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --attribute tpmSupport
```

The following is example output.

```
{
    "ImageId": "ami-0abcdef1234567890",
    "TpmSupport": {
        "Value": "v2.0"
    }
}
```

To find AMIs with NitroTPM enabled

The following example lists the IDs of the AMIs that you own with NitroTPM enabled.

```
aws ec2 describe-images \
    --owners self \
    --filters Name=tpm-support,Values=v2.0 \
    --query Images[].ImageId
```

PowerShell

To verify that NitroTPM is enabled

Use the Get-EC2Image cmdlet.

```
Get-EC2Image `
    -ImageId ami-0abcdef1234567890 | Select TpmSupport
```

If NitroTPM is enabled for the AMI, the output is as follows. If TPM is not enabled, the output is empty.

```
TpmSupport
----------
v2.0
```

Alternatively, if you are the AMI owner, you can use the Get-EC2ImageAttribute cmdlet with the `tpmSupport` attribute.

```
Get-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute tpmSupport
```

To find AMIs with NitroTPM enabled

The following example lists the IDs of the AMIs that you own with NitroTPM enabled.

```
Get-EC2Image `
    -Owner self `
    -Filter @{Name="tpm-support; Values="v2.0"} | Select ImageId
```

Enable or stop using NitroTPM on an Amazon EC2 instance

You can enable an Amazon EC2 instance for NitroTPM only at launch. After an instance is enabled for NitroTPM, you can't disable it. If you no longer need to use NitroTPM, you must configure the operating system to stop using it.

Topics

- Launch an instance with NitroTPM enabled
- Stop using NitroTPM on an instance

Launch an instance with NitroTPM enabled

When you launch an instance with the prerequisites, NitroTPM is automatically enabled on the instance. You can enable NitroTPM on an instance only at launch. For information about launching an instance, see Launch an Amazon EC2 instance.

Stop using NitroTPM on an instance

After launching an instance with NitroTPM enabled, you can't disable NitroTPM for the instance. However, you can configure the operating system to stop using NitroTPM by disabling the TPM 2.0 device driver on the instance by using the following tools:

- For **Linux instances**, use tpm-tools.
- For **Windows instances**, use the TPM management console (tpm.msc).

For more information about disabling the device driver, see the documentation for your operating system.

Verify that an Amazon EC2 instance is enabled for NitroTPM

You can verify whether an Amazon EC2 instance is enabled for NitroTPM. If NitroTPM support is enabled on the instance, the command returns `"v2.0"`. Otherwise, the `TpmSupport` field is not present in the output.

The Amazon EC2 console does not display the `TpmSupport` field.

AWS CLI

To verify whether an instance is enabled for NitroTPM

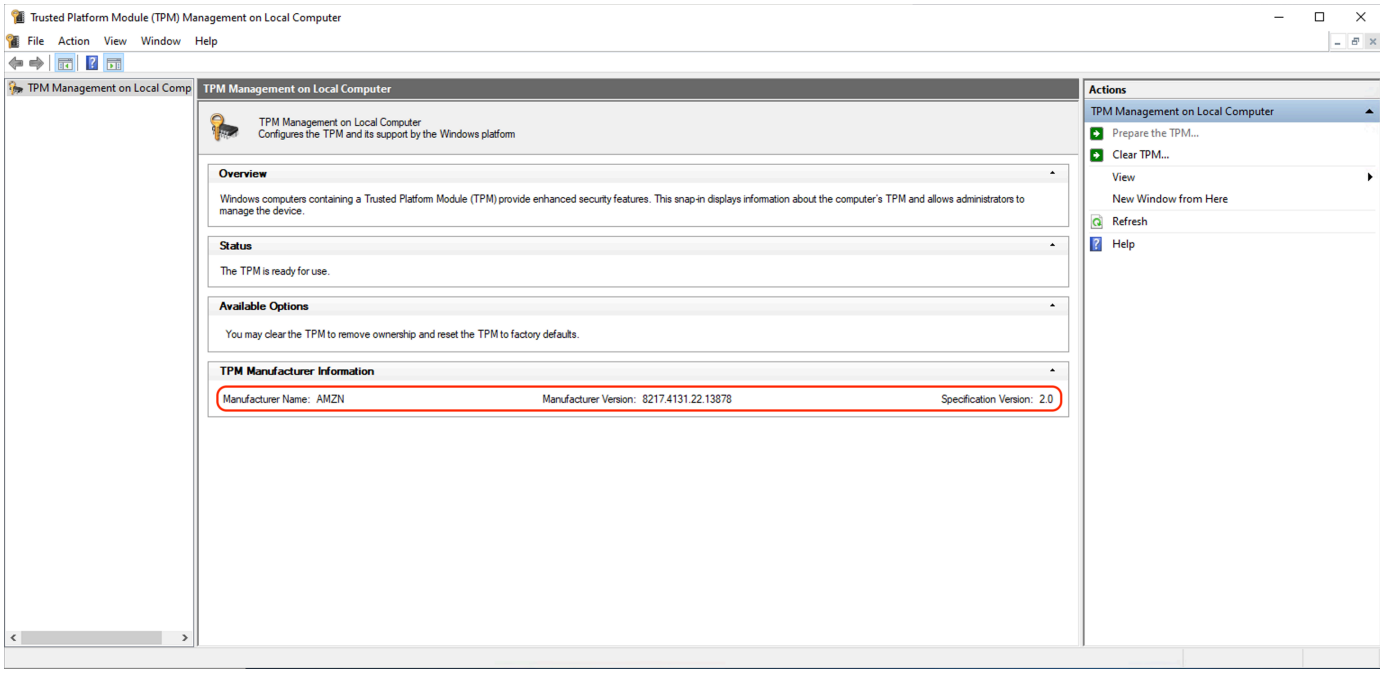
Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query Reservations[].Instances[].TpmSupport
```

PowerShell

To verify whether an instance is enabled for NitroTPM

Use the Get-EC2Instance cmdlet.



```
(Get-EC2Instance `
    -InstanceId i-1234567890abcdef0).Instances.TpmSupport
```

Verify NitroTPM access on your Windows instance

(Windows instances only) To verify whether the NitroTPM is accessible to Windows

1. Connect to your EC2 Windows instance.
2. On the instance, run the tpm.msc program.

   The **TPM Management on Local Computer** window opens.
3. Check the **TPM Manufacturer Information** field. It contains the manufacturer's name and the version of the NitroTPM on the instance.

Retrieve the public endorsement key for an EC2 instance

You can securely retrieve the public endorsement key for an instance at any time.

AWS CLI

To retrieve the public endorsement key for an instance

Use the get-instance-tpm-ek-pub command.

Example 1

The following example gets the `rsa-2048` public endorsement key in `tpmt` format for the specified instance.

```
aws ec2 get-instance-tpm-ek-pub \
    --instance-id i-1234567890abcdef0 \
    --key-format tpmt \
    --key-type rsa-2048
```

The following is the example output.

```
{
    "InstanceId": "i-01234567890abcdef",
    "KeyFormat": "tpmt",
    "KeyType": "rsa-2048",
    "KeyValue": "AAEACwADALIAIINxl2dEhLEXAMPLEUal1yT9UtduBlILZPKh2hszFGmqAAYAgABDA
    EXAMPLEAAABAOiRd7WmgtdGNoV1h/AxmW+CXExblG8pEUfNm0LOLiYnEXAMPLERqApiFa/UhvEYqN4
    Z7jKMD/usbhsQaAB1gKA5RmzuhSazHQkax7EXAMPLEzDthlS7HNGuYn5eG7qnJndRcakS+iNxT8Hvf
    0S1ZtNuItMs+Yp4SO6aU28MT/JZkOKsXIdMerY3GdWbNQz9AvYbMEXAMPLEPyHfzgVO0QTTJVGdDxh
    vxtXCOu9GYf0crbjEXAMPLEd4YTbWdDdgOKWF9fjzDytJSDhrLAOUctNzHPCd/92l5zEXAMPLEOIFA
    Ss50C0/802c17W2pMSVHvCCa9lYCiAfxH/vYKovAAE="
}
```

Example 2

The following example gets the `rsa-2048` public endorsement key in `der` format for the specified instance.

```
aws ec2 get-instance-tpm-ek-pub \
    --instance-id i-1234567890abcdef0 \
    --key-format der \
    --key-type rsa-2048
```

The following is the example output.

```
{
    "InstanceId": "i-1234567890abcdef0",
    "KeyFormat": "der",
    "KeyType": "rsa-2048",
    "KeyValue": "MIIBIjANBgEXAMPLEw0BAQEFAAOCAQ8AMIIBCgKCAQEA6JF3taEXAMPLEXWH8DGZb4

PowerShell

To retrieve the public endorsement key for an instance

Use the Get-EC2InstanceTpmEkPub cmdlet.

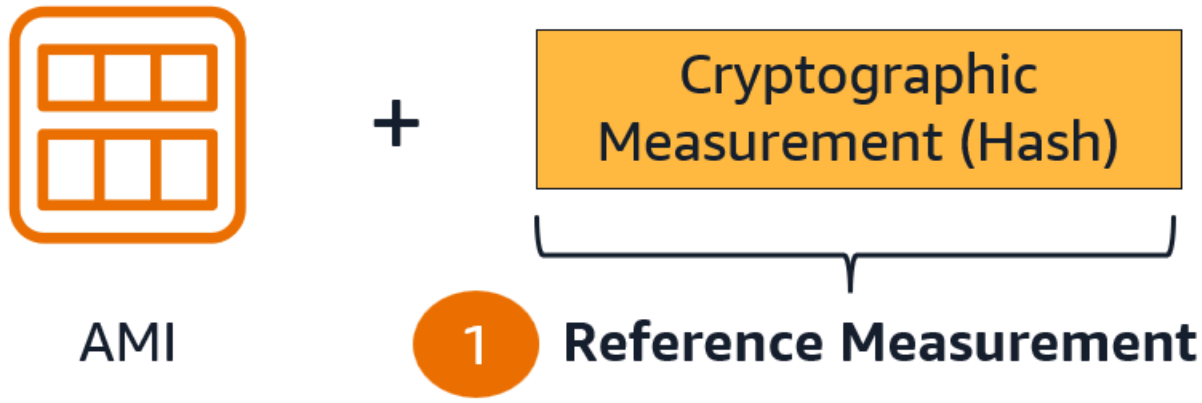
Example 1

The following example gets the `rsa-2048` public endorsement key in `tpmt` format for the specified instance.

```
Get-EC2InstanceTpmEkPub `
    -InstanceId i-1234567890abcdef0 `
    -KeyFormat tpmt `
    -KeyType rsa-2048
```

Example 2

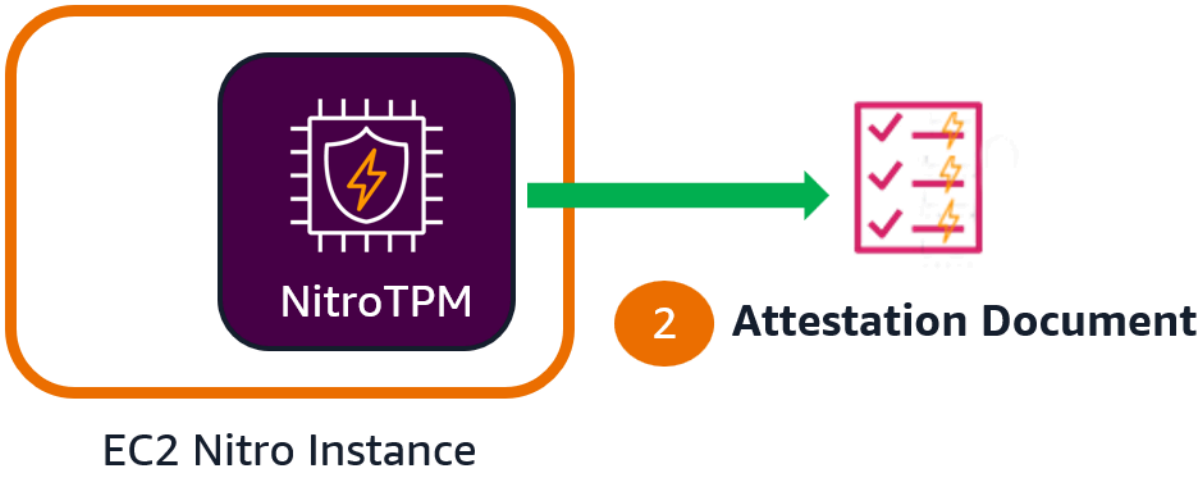
The following example gets the `rsa-2048` public endorsement key in `der` format for the specified instance.



```
Get-EC2InstanceTpmEkPub `
    -InstanceId i-1234567890abcdef0 `
    -KeyFormat der `
    -KeyType rsa-2048
```

Amazon EC2 instance attestation

Attestation is a process that allows you to cryptographically prove to any party that only trusted software, drivers, and boot processes are running on an Amazon EC2 instance. Amazon EC2 instance attestation is powered by the Nitro Trusted Platform Module (NitroTPM) and *Attestable AMIs*.



The first step to attestation is to **build an Attestable AMI** and determine the *reference measurements* of that AMI. An Attestable AMI is an AMI built from the ground up for attestation. The reference measurements are measurements of all of your software and configurations that

you have included in your AMI. For more information about how you can obtain the reference measurements, see Build the sample image description.

The next step is to launch a Nitro-TPM enabled EC2 instance with the Attestable AMI. After you have launched the instance, you can use the NitroTPM tools to generate the *Attestation Document*. Then you can compare the actual measurements of your EC2 instance from the Attestation Document against the reference measurements to check if the instance has the software and configurations that you trust.

By comparing the reference measurements generated during the Attestable AMI creation process with the measurements included in an instance's Attestation Document, you can validate that only software and code that you trust are running on the instance.

Integration with AWS KMS

To make the process of comparing measurements easier, you can use AWS Key Management Service (AWS KMS) as a verifier for Attestation Documents. With AWS KMS, you can create attestation-based KMS key policies that allow specific operations with the KMS key only if you provide an Attestation Document with measurements that match the reference measurements. To do this, you add specific condition keys to your KMS key policies that use the reference measurements as the condition key values, and then specify which KMS operations are allowed if the condition key is satisfied.

When you perform KMS operations using the KMS key, you must attach an Attestation Document to the KMS request. AWS KMS then validates the measurements from the Attestation Document against the reference measurements in the KMS key policy, and allows key access only if the measurements match.

Additionally, when you generate the Attestation Document for an instance, you must specify a public key for a key pair that you own. The specified public key is included in the Attestation Document. When AWS KMS validates the Attestation Document and allows a decryption operation, it automatically encrypts the response with the public key included in the Attestation Document before it is returned. This ensures that the response can be decrypted and used only with the matching private key for the public key included in the Attestation Document.

This ensures that only instances running trusted software and code can perform cryptographic operations using a KMS key.

Attesting isolated compute environments

In general, you can build and configure an EC2 instance to be an **isolated compute environment**, which provides no interactive access and no mechanism for your administrators and users to access the data that is being processed in the EC2 instance. With EC2 instance attestation you can prove to a third-party or service that your instance is running as an isolated compute environment. For more information, see Isolate data from your own operators.

For an example, see the sample Amazon Linux 2023 image description that creates an isolated compute environment. You can use this sample image description as a starting point and customize it to meet your requirements.

AWS shared responsibility model

NitroTPM and Attestable AMIs are building blocks that can help you to set up and configure attestation on your EC2 instances. You are responsible for configuring the AMI to meet your respective use case. For more information, see AWS Shared Responsibility Model.

Topics

- Attestable AMIs
- Prepare AWS KMS for attestation
- Get the NitroTPM Attestation Document
- Integrating with AWS KMS
- Isolate data from your own operators

Attestable AMIs

An Attestable AMI is an Amazon Machine Image (AMI) with a corresponding cryptographic hash that represents all of its contents. The hash is generated during the AMI creation process, and it is calculated based on the entire contents of that AMI, including the applications, code, and boot process.

Maintaining an Attestable State

An instance's measurements are based on its initial boot state. Any software or code changes made to the instance after launch and that persist after restarts will change the instance's measurement after restarts. If the measurements are altered, they deviate from the reference measurements of the Attestable AMI, and the instance will no longer be able to successfully attest to AWS KMS after the instance restarts. Therefore, for Attestable AMIs to be useful, instances need to return to their original boot state after they restart.

Always returning to the original boot state ensures that an instance can successfully attest after it restarts. The following utilities can be used to ensure that your instances remain attestable after restarts:

- `erofs` — Enhanced Read-Only File System. This utility ensures that your root filesystem is read-only. With this utility, writes to the filesystem, including `/etc`, `/run`, and `/var`, are stored in memory and lost when the instance is restarted, leaving the root filesystem in its original launch state. For more information, see the erofs documentation.

- `dm-verity` — Provides integrity protection for the read-only root filesystem. The utility calculates a hash of the filesystem blocks and stores it in the kernel command line. This allows the kernel to verify the integrity of the filesystem during boot. For more information, see the dm-verity documentation.

Requirements for creating Attestable AMIs

Attestable AMIs have the following requirements:

- **Base operating system** – Amazon Linux 2023 and NixOS
- **Architecture** – `x86_64` or `arm64` architecture
- **TPM support** – NitroTPM must be enabled. For more information, see Requirements for using NitroTPM with Amazon EC2 instances.
- **Boot mode** – UEFI boot mode must be enabled.

Topics

- Creating Attestable AMIs
- Build the sample Amazon Linux 2023 image description
- Sample Amazon Linux 2023 image description
- Customize the sample Amazon Linux 2023 image description for your workload
- Compute PCR measurements for a custom AMI

Creating Attestable AMIs

To create an Attestable AMI, you will need to use Amazon Linux 2023 with KIWI Next Generation (KIWI NG). Amazon Linux 2023 provides all of the software and utilities needed to build an Attestable AMI using KIWI NG.

KIWI NG is an open-source tool for building pre-configured Linux-based images. KIWI NG uses XML *image descriptions* that define the contents of an image. The image description specifies the base operating system, software, kernel configuration, and scripts to run to build a ready-to-use AMI for a specific use case.

During AMI build time, you need to use the `nitro-tpm-pcr-compute` utility to generate the reference measurements based on the Unified Kernel Image (UKI) generated by KIWI NG. For more

information about using the `nitro-tpm-pcr-compute` utility, see Compute PCR measurements for a custom AMI.

AWS provides a sample Amazon Linux 2023 image description that includes all configurations needed to configure an EC2 instance in an isolated compute environment. For more information, see Build the sample Amazon Linux 2023 image description.

Build the sample Amazon Linux 2023 image description

AWS provides a sample Amazon Linux 2023 image description that you can use as a starting point for creating your own custom Attestable AMIs for your workloads. The sample image description includes Amazon Linux 2023 as the base operating system, `dm-verity` and `erofs` configurations for filesystem immutability, and it removes all interactive access (such as SSH, EC2 instance connect, and serial console) to create an isolated compute environment. For more information about the sample image description, see the Github repo.

The sample image description automatically installs the NitroTPM tools (`nitro-tpm-pcr-compute` and `nitro-tpm-attest`) in the built image in the `/usr/bin/` directory. This ensures that the tools are preinstalled on instances launched from the AMI.

The sample image description includes a script, `edit_boot_install.sh`, which includes the commands needed to generate the reference measurements. The script mounts the raw disk image file (`.raw`) created by KIWI NG to a loopback device, locates the UKI, which has the `.efi` file extension, and then runs the `nitro-tpm-pcr-compute` utility to generate the reference measurements for the AMI. The script is automatically executed by KIWI NG during build time.

This tutorial shows you how to build the sample image description to create an Attestable AMI.

For more information about creating your own image descriptions, see the following KIWI NG documentation:

- Quick Start
- Image Description
- Sample Amazon Linux 2023 image description

Prerequisites

Your IAM identity must have the following permissions to complete this tutorial:

- ebs:CompleteSnapshot, ebs:StartSnapshot, and ebs:PutSnapshotBlock on arn:aws:ec2:*::snapshot/*
- ec2:RegisterImage on all resources

To build the sample Amazon Linux 2023 image description using KIWI NG

1. Launch an Amazon EC2 instance using the latest AL2023 AMI. To ensure that your instance has enough storage space to build the AMI, ensure that you provision at least 12 GB of storage.
2. Install the required dependencies. The following command installs the following utilities:

   - kiwi-cli
   - veritysetup
   - erofs-utils
   - aws-nitro-tpm-tools

   ```
   sudo dnf install -y kiwi-cli python3-kiwi kiwi-systemdeps-core python3-poetry-core
    qemu-img veritysetup erofs-utils git cargo aws-nitro-tpm-tools
   ```
3. Install the coldsnap utility. This utility enables you to create Amazon EBS snapshots from raw image data. You'll use this utility to create an EBS snapshot from the raw disk image file created by KIWI NG.

   ```
   git clone https://github.com/awslabs/coldsnap.git
   cd coldsnap
   cargo install --locked coldsnap
   cd ..
   ```
4. Get the sample image description files.

   ```
   sudo dnf install kiwi-image-descriptions-examples
   ```

   The sample image description files are downloaded to the following directory: /usr/share/kiwi-image-descriptions-examples/al2023/attestable-image-example
5. Build the sample image description using the KIWI NG system build command. The following command creates a raw disk image file in the ./image directory.

   ```
   sudo kiwi-ng \
   ```

```
--color-output \
--loglevel 0 \
system build \
--description /usr/share/kiwi-image-descriptions-examples/al2023/attestable-image-
example \
--target-dir ./image
```

For more information, see the kiwi-ng system build documentation.

6. Get the reference measurements for the AMI. The measurements are generated by the `nitro-tpm-pcr-compute` utility during image build time in the previous step. You can locate the reference measurements in the following file: `./image/pcr_measurements.json`.

   The measurements are provided in the following JSON format:

   ```
   {
     "Measurements": {
       "HashAlgorithm": "SHA384 { ... }",
       "PCR4": "PCR4_measurement",
       "PCR7": "PCR7_measurement",
       "PCR12": "PCR12_measurement"
     }
   }
   ```

7. Use the `coldsnap` utility to upload the raw disk image created by KIWI NG to an EBS snapshot. The command returns the snapshot ID. Make a note of the ID, you'll need it for the next step.

   ```
   SNAPSHOT=$(.cargo/bin/coldsnap upload ./image/al2023*.raw)
   echo "Created snapshot: $SNAPSHOT"
   ```

   For more information about the `coldsnap` utility, see the coldsnap GitHub repo.

8. Register a TPM 2.0-enabled AMI with UEFI boot mode using the snapshot from the previous step. For `--architecture`, specify `x86_64` for Intel, or `arm64` for Graviton.

   ```
   aws ec2 register-image \
   --name "attestable_isolated_al2023_ami" \
   --virtualization-type hvm \
   --boot-mode uefi \
   --architecture x86_64|arm64 \
   --root-device-name /dev/xvda \
   ```

```
--block-device-mappings DeviceName=/dev/xvda,Ebs={SnapshotId=${SNAPSHOT}} \
--tpm-support v2.0 \
--ena-support
```

Sample Amazon Linux 2023 image description

The sample Amazon Linux 2023 image description has the following characteristics:

1. **Unified Kernel Image (UKI) boot** — Boot using a single, signed binary that combines the kernel, `initrd`, and boot parameters into one immutable image.
2. **Read-only root filesystem** — Use Enhanced Read-Only File System (`erofs`) with dm-verity protection to ensure that the root filesystem cannot be modified and maintains cryptographic integrity verification.
3. **Ephemeral overlay filesystem** — Create a temporary overlay filesystem that allows temporary writes to directories like `/etc`, `/run`, and `/var`. Since this overlay filesystem exists only in memory, all changes are automatically lost when the instance reboots, ensuring the system returns to its original trusted state.
4. **Disabled remote access methods** — Remove the following remote access mechanisms to prevent remote access:

Access Method	Description	Image description implementation
SSH	Excludes OpenSSH server. Makes the instance inherently incapable of handling SSH traffic.	Ignore the `openssh-server` package *
User Data	Removes Cloud-init. Eliminates the ability for operators to provide user data to instances and run boot-time scripts.	Ignore the `cloud-init` and `cloud-init-cfg-ec2` packages *
Chrony	Disables the chrony command port. Prevents operators from running chrony commands on running instances.	Ignore the `amazon-ch`

Access Method	Description	Image description implementation
		`rony-config` package *
MOTD	Removes MOTD package. Eliminates the ability for operators to change messages or functionality on running instances.	Ignore the `update-motd` package *
AWS SSM	Removes the AWS SSM agent. Prevents remote access to running instances using AWS SSM.	Ignore the `amazon-ssm-agent` package *
EC2 Instance Connect	Removes EC2 Instance Connect package. Disables SSH access using this tool.	Ignore the `ec2-instance-connect` package *
Serial Console	Disables serial console. Ensures that console access is unavailable for running instances and removes the operators' ability to login to the serial console.	Disabled through kernel command line parameter

* For more information, see Image Description Elements.

Customize the sample Amazon Linux 2023 image description for your workload

You can customize the sample Amazon Linux 2023 image description and include the software packages, scripts, and files that are needed for your specific workload. Customizations are achieved by adding to or modifying various elements in the KIWI NG image description.

Topics

- Repository management
- Package management

- Adding files and directories
- Adding custom scripts

Repository management

By default, the sample image description includes a single `<repository>` element that points to a mirror endpoint for the Amazon Linux 2023 core repositories. If needed, you can add references to other repositories from which to install your required software.

The sample image description uses the `dnf` package manager, as defined in the `<packagemanager>` element.

For more information about adding repositories, see Setting up Repositories.

Package management

By default, the sample image description includes all of the packages needed to create an Amazon Linux 2023 Attestable AMI for an isolated compute environment with an `erofs` read-only file system.

You can include additional software packages in the image description by adding them to the `<packages>` element in the image description. The `<packages>` element defines all of the software that should be installed into the AMI.

You can also use the `<packages>` element to uninstall or delete specific software packages.

For more information about adding or removing packages in the image description, see Adding and Removing Packages.

Adding files and directories

The sample image description includes an overlay tree directory (`/root/`). The overlay tree directory is a directory that contains files and directories that will be copied into the image during the image build process. Any files and directories that you place into the overlay tree directory will be copied directly into the root filesystem of the image during the image building process.

The overlay tree directory is copied into the image after all the packages have been installed. New files are added and existing files are overwritten.

Adding custom scripts

The sample image description includes a single custom script, `edit_boot_install.sh`. This script includes the commands that are needed to run the `nitro-tpm-pcr-compute` utility, which generates the reference measurements based on the image content. This script is called immediately after the bootloader is installed.

If needed, you can include your own custom scripts in the image description to perform tasks or configurations during the image build process or at first boot of the image. Using scripts enables you to customize your images in ways that cannot be achieved using the image description alone.

To include custom scripts in your image description, you need to name them correctly based on the type of script, and add them to the same directory as the `appliance.kiwi` file. KIWI NG automatically detects and executes the scripts if they are named correctly and placed in the correct location, without the need to explicitly reference them in the image description file.

For more information about the scripts supported by KIWI NG, see User-Defined Scripts.

Compute PCR measurements for a custom AMI

The `nitro-tpm-pcr-compute` utility enables you to generate the reference measurements for an Attestable AMI during build time based on its Unified Kernel Image (UKI).

The sample Amazon Linux 2023 image description automatically installs the utility in the built image in the `/usr/bin/` directory. The sample image description also includes a script with the commands needed to run the utility to generate the reference measurements during image build time. If you are using the sample image description, you don't need to install the utility or run it manually. For more information, see Build the sample Amazon Linux 2023 image description.

Install the `nitro-tpm-pcr-compute` utility

If you are using Amazon Linux 2023, you can install the `nitro-tpm-pcr-compute` utility from the Amazon Linux repository as follows.

```
sudo yum install aws-nitro-tpm-tools
```

The tools are installed in the `/usr/bin` directory.

Use the `nitro-tpm-pcr-compute` utility

The utility provides a single command, `nitro-tpm-pcr-compute`, for generating the reference measurements.

When you run the command, you must specify the following:

- Unified kernel image (`UKI.efi`) — Required for Standard boot and UEFI.

To generate the reference measurements for an Attestable AMI:

Use the following command and parameters:

```
/usr/bin/nitro-tpm-pcr-compute \
--image UKI.efi
```

The utility returns the reference measurements in the following JSON format:

```
{
  "Measurements": {
    "HashAlgorithm": "SHA384 { ... }",
    "PCR4": "PCR4_measurement",
    "PCR7": "PCR7_measurement",
    "PCR12": "PCR12_measurement"
  }
}
```

For a practical example of how to use the `nitro-tpm-pcr-compute` utility, see the `edit_boot_install.sh` script included in the sample Amazon Linux 2023 image description.

Prepare AWS KMS for attestation

> **Note**
>
> If you are attesting to a third-party service, you must build your own custom mechanisms for receiving, parsing, and validating Attestation Documents. For more information, see Validate a NitroTPM Attestation Document.

After you have created your Attestable AMI, you should have reference measurements that you can use to validate requests from an Amazon EC2 instance. AWS KMS provides built-in support for attestation with NitroTPM.

For the AWS KMS key that you used to encrypt your secret data, add a key policy that allows key access only if API requests include an Attestation Document with measurements that match the

reference measurements you generated during the Attestable AMI creation process. Use PCR4 and PCR12 measurements for standard boot or PCR7 measurements for Secure Boot. This ensures that only requests from instances launched using the Attestable AMI can perform cryptographic operations using the AWS KMS key.

AWS KMS provides `kms:RecipientAttestation:NitroTPMPCR4`, `kms:RecipientAttestation:NitroTPMPCR7`, and `kms:RecipientAttestation:NitroTPMPCR12` condition keys that enable you to create attestation-based conditions for NitroTPM KMS key policies. For more information, see Condition keys for NitroTPM.

For example, the following AWS KMS key policy allows key access only if the request originates from an instance with the `MyEC2InstanceRole` instance profile attached, and if the request includes an Attestation Document with specific PCR 4 and PCR 12 values.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Allow requests from instances with attested AMI only",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/MyEC2InstanceRole"
      },
      "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey",
        "kms:GenerateRandom"
      ],
      "Resource": "*",
      "Condition": {
        "StringEqualsIgnoreCase": {

 "kms:RecipientAttestation:NitroTPMPCR4":"EXAMPLE6b9b3d89a53b13f5dfd14a1049ec0b80a9ae4b159adde4

 "kms:RecipientAttestation:NitroTPMPCR12":"000000000000000000000000000000000000000000000000000
        }
      }
    }
  ]
}
```

Get the NitroTPM Attestation Document

The Attestation Document is a key component of the NitroTPM attestation process. It contains a series of cryptographic measurements that can be used to verify the identity of the instance and to prove that it is running only trusted software. You can use the Attestation Document with AWS KMS, which provides built-in support for NitroTPM attestation, or to build your own cryptographic attestation mechanisms.

The `nitro-tpm-attest` utility enables you to retrieve a signed NitroTPM Attestation Document for an Amazon EC2 instance during runtime.

The sample Amazon Linux 2023 image description automatically installs the utility in the built image in the `/usr/bin/` directory. This ensures that the utility is preinstalled on instances launched using the AMI. You don't need to manually install the utility. For more information, see Build the sample Amazon Linux 2023 image description.

Topics

- Install the nitro-tpm-attest utility
- Use the nitro-tpm-attest utility
- NitroTPM Attestation Document contents
- Validate a NitroTPM Attestation Document

Install the `nitro-tpm-attest` utility

If you are using Amazon Linux 2023, you can install the `nitro-tpm-attest` utility from the Amazon Linux repository as follows.

```
sudo yum install aws-nitro-tpm-tools
```

Use the `nitro-tpm-attest` utility

The utility provides a single command, `nitro-tpm-attest`, for retrieving the Attestation Document. The command returns the Attestation Document encoded in Concise Binary Object Representation (CBOR) and signed using CBOR Object Signing and Encryption (COSE).

When you run the command, you can specify the following optional parameters:

- `public-key` — A public key that can be used by AWS KMS or an external service to encrypt response data before it is returned. This ensures that only the intended recipient, that has possession of the private key, can decrypt the data. For example, if you are attesting with AWS KMS, the service encrypts the plaintext data with the public key in the Attestation Document, and returns the resulting ciphertext in the `CiphertextForRecipient` field in the response. Only RSA keys are supported.
- `user-data` — The user data can be used to deliver any additional signed data to an external service. This user data can be used to complete an agreed protocol between the requesting instance and the external service. Not used for attestation with AWS KMS.
- `nonce` — The nonce can be used to set up challenge-response authentication between the instance and the external service to help prevent impersonation attacks. Using a nonce enables the external service to verify that it is interacting with a live instance and not an impersonator that is reusing an old Attestation Document. Not used for attestation with AWS KMS.

To retrieve the Attestation Document

Use the following command and optional parameters:

```
/usr/bin/nitro-tpm-attest \
--public-key rsa_public_key \
--user-data user_data \
--nonce nonce
```

For a complete example that shows how to generate an RSA key pair, and how to request an attestation with the public key, see the nitro-tpm-attest GitHub repo.

NitroTPM Attestation Document contents

An Attestation Document is generated by the NitroTPM and it is signed by the Nitro Hypervisor. It includes a series of platform configuration registers (PCR) values related to an Amazon EC2 instance. The following PCRs are included in the Attestation Document:

> **Important**
>
> PCR0 and PCR1 are generally used to measure the initial boot code, which is controlled by AWS. To allow safe updates of early boot code, these PCRs will always contain constant values.

- PCR0 — Core System Firmware Executable Code
- PCR1 — Core System Firmware Data
- PCR2 — Extended or pluggable executable code
- PCR3 — Extended or pluggable Firmware Data
- PCR4 — Boot Manager Code
- PCR5 — Boot Manager Code Configuration and Data and GPT Partition Table
- PCR6 — Host Platform Manufacturer Specifics
- PCR7 — Secure Boot Policy
- PCR8 - 15 — Defined for use by the Static Operating System
- PCR16 — Debug
- PCR23 — Application Support

PCR4, **PCR7**, and **PCR12** specifically are used to validate that an instance was launched using an Attestable AMI. PCR4 and PCR12 can be used to validate with standard boot, and PCR7 can be used to validate with Secure Boot.

- **PCR4 (Boot Manager Code)** — When an instance starts, the NitroTPM creates cryptographic hashes of all the binaries executed by its UEFI environment. With Attestable AMIs, these boot binaries embed hashes that prevent future loading of binaries that do not have matching hashes. This way, the single boot binary hash can describe exactly what code an instance will execute.
- **PCR7 (Secure Boot Policy)** — UEFI boot binaries can be signed with a UEFI Secure Boot signing key. When UEFI Secure Boot is enabled, UEFI will prevent execution of UEFI boot binaries that do not match the configured policy. PCR7 contains a hash of the instance's UEFI Secure Boot policy.

  If you need to maintain a single KMS policy that persists across instance updates, you can create a policy that validates against PCR7 to validate a UEFI Secure Boot certificate. During creation of an Attestable AMI, you can then sign the boot binary with your certificate and install it as the only permitted certificate in the AMI's UEFI-data. Keep in mind that this model requires you to still generate a new certificate, install it in your policy and update AMIs if you want to prevent instances launched from old (untrusted) AMIs from passing your KMS policy.
- **PCR12** — Contains the hash of the command line passed to the UEFI boot binary. Required in conjunction with PCR4 for standard boot to validate the command line was not modified.

Validate a NitroTPM Attestation Document

> **Note**
>
> This topic is intended for users who are using a third-party key management service, and need to build their own Attestation Document validation mechanisms.

This topic provides a detailed overview of the entire NitroTPM attestation flow. It also discusses what is generated by the AWS Nitro system when an Attestation Document is requested, and explains how a key management service should process an Attestation Document.

Topics

- The Attestation Document
- Attestation Document validation

The purpose of attestation is to prove that an instance is a trustworthy entity, based on the code and configuration that it is running. The root of trust for the instance resides within the AWS Nitro system, which provides Attestation Documents.

Attestation Documents are signed by the AWS Nitro Attestation Public Key Infrastructure (PKI), which includes a published certificate authority that can be incorporated into any service.

The Attestation Document

Attestation Documents are encoded in Concise Binary Object Representation (CBOR), and signed using CBOR Object Signing and Encryption (COSE).

For more information about CBOR, see RFC 8949: Concise Binary Object Representation (CBOR).

Attestation Document specification

The following shows the structure of an Attestation Document.

```
AttestationDocument = {
    module_id: text,                    ; issuing Nitro hypervisor module ID
    timestamp: uint .size 8,            ; UTC time when document was created, in
                                        ; milliseconds since UNIX epoch
```

```
    digest: digest,                     ; the digest function used for calculating the
                                        ; register values
    nitrotpm_pcrs: { + index => pcr },  ; map of PCRs at the moment the Attestation
 Document was generated
    certificate: cert,                  ; the public key certificate for the public
 key
                                        ; that was used to sign the Attestation
 Document
    cabundle: [* cert],                 ; issuing CA bundle for infrastructure
 certificate
    ? public_key: user_data,            ; an optional DER-encoded key the attestation
                                        ; consumer can use to encrypt data with
    ? user_data: user_data,             ; additional signed user data, defined by
 protocol
    ? nonce: user_data,                 ; an optional cryptographic nonce provided by
 the
                                        ; attestation consumer as a proof of
 authenticity
}

cert = bytes .size (1..1024)       ; DER encoded certificate
user_data = bytes .size (0..1024)
pcr = bytes .size (32/48/64)       ; PCR content
index = 0..31
digest = "SHA384"
```

The optional parameters in the Attestation Document (`public_key`, `user_data`, and `nonce`) can be used to establish a custom validation protocol between an attesting instance and the external service.

Attestation Document validation

When you request an Attestation Document from the Nitro Hypervisor, you receive a binary blob that contains the signed Attestation Document. The signed Attestation Document is a CBOR-encoded, COSE-signed (using the COSE_Sign1 signature structure) object. The overall validation process includes the following steps:

1. Decode the CBOR object and map it to a COSE_Sign1 structure.
2. Extract the Attestation Document from the COSE_Sign1 structure.
3. Verify the certificate's chain.
4. Ensure that the Attestation Document is properly signed.

Attestation Documents are signed by the AWS Nitro Attestation PKI, which includes a root certificate for the commercial AWS partitions. The root certificate can be downloaded from https://aws-nitro-enclaves.amazonaws.com/AWS_NitroEnclaves_Root-G1.zip, and it can be verified using the following fingerprint.

```
64:1A:03:21:A3:E2:44:EF:E4:56:46:31:95:D6:06:31:7E:D7:CD:CC:3C:17:56:E0:98:93:F3:C6:8F:79:BB:5B
```

The root certificate is based on an AWS Certificate Manager Private Certificate Authority (AWS Private CA) private key and it has a lifetime of 30 years. The subject of the PCA has the following format.

```
CN=aws.nitro-enclaves, C=US, O=Amazon, OU=AWS
```

Topics

- COSE and CBOR
- Semantic validity
- Certificate validity
- Certificate chain validity

COSE and CBOR

Usually, the COSE_Sign1 signature structure is used when only one signature is going to be placed on a message. The parameters dealing with the content and the signature are placed in the protected header rather than having the separation of COSE_Sign. The structure can be encoded as either tagged or untagged, depending on the context it will be used in. A tagged COSE_Sign1 structure is identified by the CBOR tag 18.

The CBOR object that carries the body, the signature, and the information about the body and signature is called the COSE_Sign1 structure. The COSE_Sign1 structure is a CBOR array. The array includes the following fields.

```
[
  protected:   Header,
  unprotected: Header,
  payload:     This field contains the serialized content to be signed,
  signature:   This field contains the computed signature value.
]
```

In the context of an Attestation Document, the array includes the following.

```
18(/* COSE_Sign1 CBOR tag is 18 */
    {1: -35}, /* This is equivalent with {algorithm: ECDS 384} */
    {}, /* We have nothing in unprotected */
    $ATTESTATION_DOCUMENT_CONTENT /* Attestation Document */,
    signature /* This is the signature */
)
```

For more information about CBOR, see RFC 8949: Concise Binary Object Representation (CBOR).

Semantic validity

An Attestation Document will always have their CA bundle in the following order.

```
[ ROOT_CERT - INTERM_1 - INTERM_2 .... - INTERM_N]
      0          1          2             N - 1
```

Keep this ordering in mind, as some existing tools, such as Java's CertPath from Java PKI API Programmer's Guide, might require them to be ordered differently.

To validate the certificates, start from the Attestation Document CA bundle and generate the required chain, Where TARGET_CERT is the certificate in the Attestation Document.

```
[TARGET_CERT, INTERM_N, ..... , INTERM_2, INTERM_1, ROOT_CERT]
```

Certificate validity

For all of the certificates in the chain, you must ensure that the current date falls within the validity period specified in the certificate.

Certificate chain validity

In general, a chain of multiple certificates might be needed, comprising a certificate of the public key owner signed by one CA, and zero or more additional certificates of CAs signed by other CAs. Such chains, called certification paths, are required because a public key user is only initialized with a limited number of assured CA public keys. Certification path validation procedures for the internet PKI are based on the algorithm supplied in X.509. Certification path processing verifies the binding between the subject distinguished name and/or subject alternative name and subject public key. The binding is limited by constraints that are specified in the certificates that

comprise the path and inputs that are specified by the relying party. The basic constraints and policy constraint extensions allow the certification path processing logic to automate the decision making process.

> **Note**
>
> CRL must be disabled when doing the validation.

Using Java, starting from the root path and the generated certificate chain, the chain validation is as follows.

```
validateCertsPath(certChain, rootCertficate) {
    /* The trust anchor is the root CA to trust */
    trustAnchors.add(rootCertificate);

    /* We need PKIX parameters to specify the trust anchors
     * and disable the CRL validation
     */
    validationParameters = new PKIXParameters(trustAnchors);
    certPathValidator = CertPathValidator.getInstance(PKIX);
    validationParameters.setRevocationEnabled(false);

    /* We are ensuring that certificates are chained correctly */
    certPathValidator.validate(certPath, validationParameters);
}
```

Integrating with AWS KMS

Your instance should have an application that can make AWS KMS API requests with the Attestation Document retrieved from the NitroTPM. When you make a request with an Attestation Document, AWS KMS validates the measurements in the provided Attestation Document against the reference measurements in the KMS key policy. Requests are allowed only if the measurements in the Attestation Document match the reference measurements in the KMS key policy.

When you call the Decrypt, DeriveSharedSecret, GenerateDataKey, GenerateDataKeyPair, or GenerateRandom API operations with an Attestation Document, these APIs encrypt the plaintext in the response under the public key from the Attestation Document, and return ciphertext instead of plaintext. This ciphertext can be decrypted only by using the matching private key that was generated in the instance.

For more information, see the Cryptographic attestation for NitroTPM in the *AWS Key Management Service Developer Guide*.

> **Note**
>
> If you are attesting to a third-party service, you must build your own custom mechanisms for receiving, parsing, and validating Attestation Documents. For more information, see Validate a NitroTPM Attestation Document.

Isolate data from your own operators

The AWS Nitro System has zero operator access. There is no mechanism for any AWS system or person to log in to Amazon EC2 Nitro hosts, access the memory of EC2 instances, or access any customer data stored on local encrypted instance storage or remote encrypted Amazon EBS volumes.

When processing highly sensitive data, you might consider restricting access to that data by preventing even your own operators from accessing the EC2 instance.

You can create custom Attestable AMIs that are configured to provide an isolated compute environment. The AMI configuration depends on your workload and application requirements. Consider these best practices when building your AMI to create an isolated compute environment.

- **Remove all interactive access** to prevent your operators or users access to the instance.
- **Ensure that only trusted software and code** is included in the AMI.
- **Configure a network firewall** within the instance to block access.
- **Ensure read-only and immutable states** for all storage and file systems.
- **Restrict instance access** to authenticated, authorized, and logged API calls.

Updating Attestable AMIs that have no interactive access

After you launch an instance using an isolated compute environment AMI, there is no way for any user or operator to connect to the instance. This means that there is no way to install or update any software on the instance after launch.

If new software or a software update is required, you must create a new Attestable AMI that includes the required software or software updates. Then, use that AMI to launch a new instance,

or to perform a root volume replacement on the original instance. Any software changes made to the AMI will result in a new hash being generated.

The following actions will result in a change to the reference measurements in the NitroTPM Attestation Document:

- Stopping and starting an instance launched with an Attestable AMI
- Performing a root volume replacement with a different AMI

If you perform any of these actions, you must then update your attestation service with the new reference measurements. For example, you must update your KMS key policy to the new reference measurements if you are using AWS KMS for attestation.

An instance retains its NitroTPM key material for the entire instance lifecycle, and persists through stop/starts and root volume replacement operations.

Credential Guard for Windows instances

The AWS Nitro System supports Credential Guard for Amazon Elastic Compute Cloud (Amazon EC2) Windows instances. Credential Guard is a Windows virtualization-based security (VBS) feature that enables the creation of isolated environments to protect security assets, such as Windows user credentials and code integrity enforcement, beyond Windows kernel protections. When you run EC2 Windows instances, Credential Guard uses the AWS Nitro System to protect Windows login credentials from being extracted from the operating system's memory.

Contents

- Prerequisites
- Launch a supported instance
- Disable memory integrity
- Turn on Credential Guard
- Verify that Credential Guard is running

Prerequisites

Your Windows instance must meet the following prerequisites to use Credential Guard.

Amazon Machine Images (AMIs)

The AMI must be preconfigured to enable NitroTPM and UEFI Secure Boot. For more information on supported AMIs, see the section called “Requirements”.

Memory integrity

Memory integrity, also known as *hypervisor-protected code integrity (HVCI)* or *hypervisor enforced code integrity*, isn't supported. Before you turn on Credential Guard, you must ensure this feature is disabled. For more information, see Disable memory integrity.

Instance types

The following instance types support Credential Guard across all sizes unless noted otherwise: `C5`, `C5d`, `C5n`, `C6i`, `C6id`, `C6in`, `C7i`, `C7i-flex`, `M5`, `M5d`, `M5dn`, `M5n`, `M5zn`, `M6i`, `M6id`, `M6idn`, `M6in`, `M7i`, `M7i-flex`, `R5`, `R5b`, `R5d`, `R5dn`, `R5n`, `R6i`, `R6id`, `R6idn`, `R6in` `R7i`, `R7iz`, `T3`.

Note

- Though NitroTPM has some required instance types in common, the instance type must be one of the preceding instance types to support Credential Guard.
- Credential Guard isn't supported for:
  - Bare metal instances.
  - The following instance types: `C7i.48xlarge`, `M7i.48xlarge`, and `R7i.48xlarge`.

For more information about instance types, see the Amazon EC2 Instance Types Guide.

Launch a supported instance

You can use the Amazon EC2 console or AWS Command Line Interface (AWS CLI) to launch an instance which can support Credential Guard. You will need a compatible AMI ID for launching your instance which is unique for each AWS Region.

Tip

You can use the following link to discover and launch instances with compatible Amazon provided AMIs in the Amazon EC2 console:

https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/v2/home?#Images:visibility=public-images;v=3;search=:TPM-Windows_Server;ownerAlias=amazon

Console

To launch an instance

Follow the steps to launch an instance, specifying a supported instance type and a preconfigured Windows AMI.

AWS CLI

To launch an instance

Use the run-instances command to launch an instance using a supported instance type and preconfigured Windows AMI.

```
aws ec2 run-instances \
    --image-id resolve:ssm:/aws/service/ami-windows-latest/TPM-Windows_Server-2022-English-Full-Base \
    --instance-type c6i.large \
    --region us-east-1 \
    --subnet-id subnet-0abcdef1234567890
    --key-name key-name
```

PowerShell

To launch an instance

Use the New-EC2Instance command to launch an instance using a supported instance type and preconfigured Windows AMI.

```
New-EC2Instance `
    -ImageId resolve:ssm:/aws/service/ami-windows-latest/TPM-Windows_Server-2022-English-Full-Base `
    -InstanceType c6i.large `
    -Region us-east-1 `
    -SubnetId subnet-0abcdef1234567890 `
    -KeyName key-name
```

Disable memory integrity

You can use the Local Group Policy Editor to disable memory integrity in supported scenarios. The following guidance can be applied for each configuration setting under **Virtualization Based Protection of Code Integrity**:

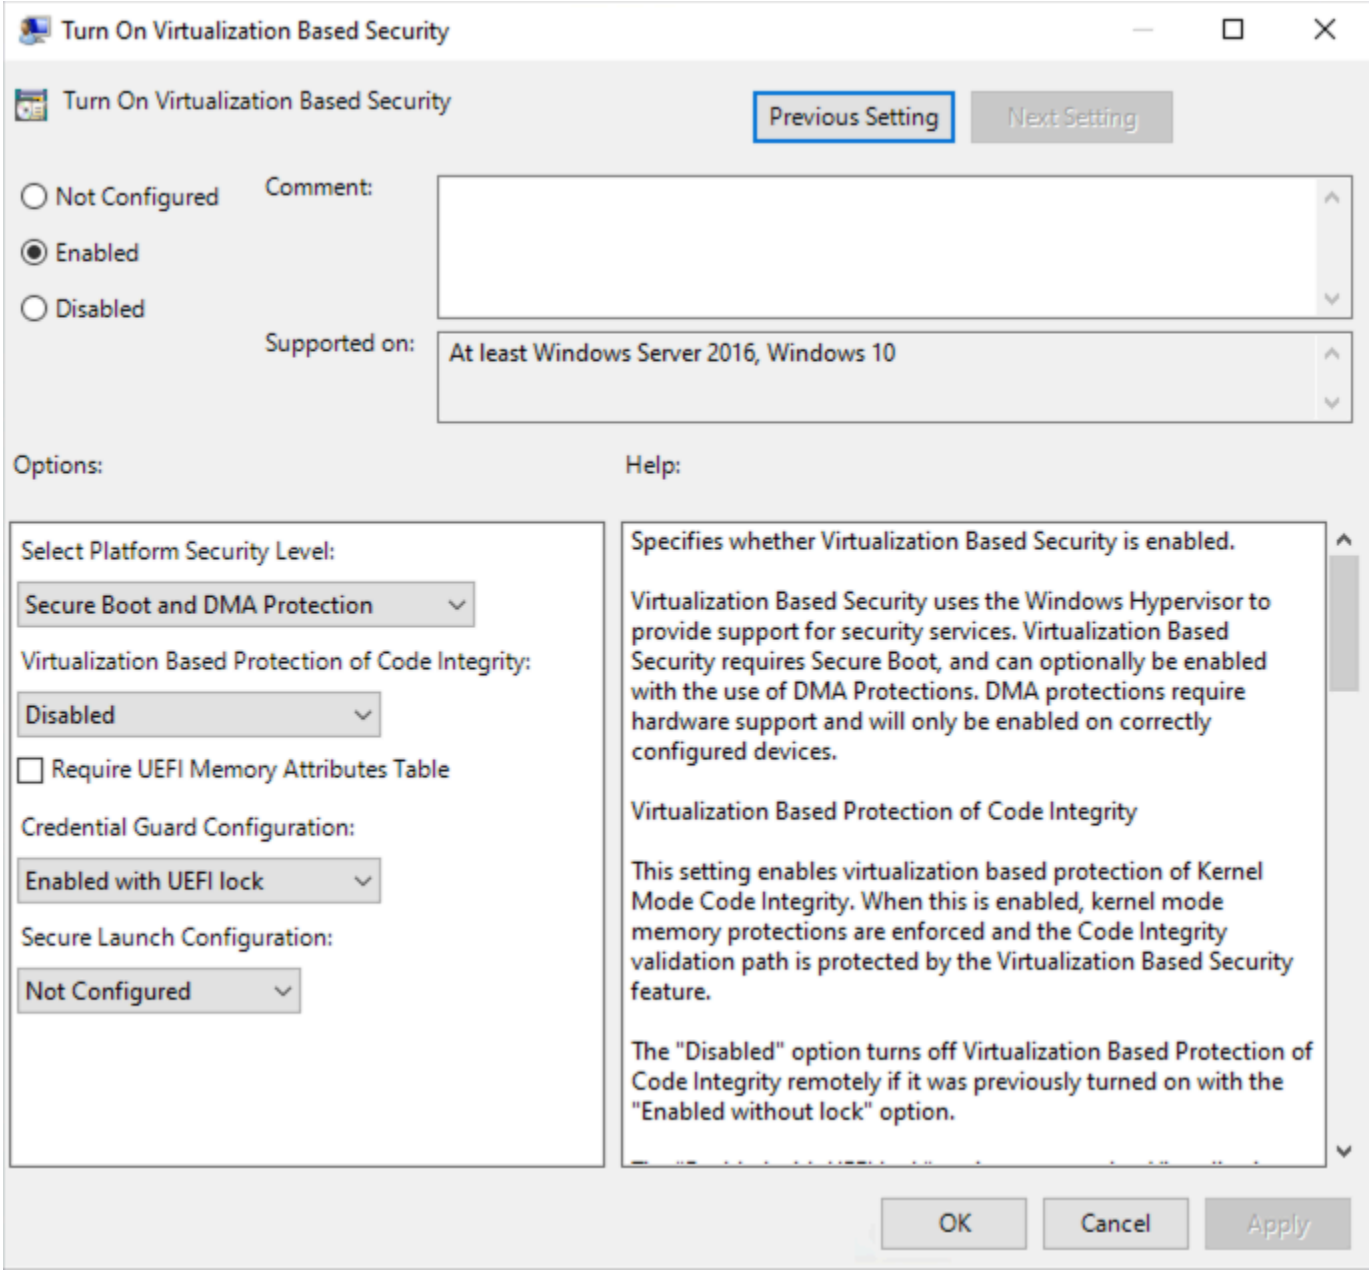
- **Enabled without lock** – Modify the setting to **Disabled** to disable memory integrity.
- **Enabled with UEFI lock** – Memory integrity has been enabled with UEFI lock. Memory integrity can't be disabled after it has been enabled with UEFI lock. We recommend creating a new instance with memory integrity disabled and terminating the unsupported instance if it's not in use.

To disable memory integrity with the Local Group Policy Editor

1. Connect to your instance as a user account with administrator privileges using the Remote Desktop Protocol (RDP). For more information, see the section called “Connect using an RDP client”.
2. Open the Start menu and search for **cmd** to start a command prompt.
3. Run the following command to open the Local Group Policy Editor: `gpedit.msc`
4. In the Local Group Policy Editor, choose **Computer Configuration**, **Administrative Templates**, **System**, **Device Guard**.
5. Select **Turn On Virtualization Based Security**, then select **Edit policy setting**.
6. Open the settings drop-down for **Virtualization Based Protection of Code Integrity**, choose **Disabled**, then choose **Apply**.
7. Reboot the instance to apply the changes.

Turn on Credential Guard

After you have launched a Windows instance with a supported instance type and compatible AMI, and confirmed that memory integrity is disabled, you can turn on Credential Guard.



> **Important**
>
> Administrator privileges are required to perform the following steps to turn on Credential Guard.

To turn on Credential Guard

1. Connect to your instance as a user account with administrator privileges using the Remote Desktop Protocol (RDP). For more information, see the section called "Connect using an RDP client".
2. Open the Start menu and search for **cmd** to start a command prompt.
3. Run the following command to open the Local Group Policy Editor: `gpedit.msc`
4. In the Local Group Policy Editor, choose **Computer Configuration**, **Administrative Templates**, **System**, **Device Guard**.
5. Select **Turn On Virtualization Based Security**, then select **Edit policy setting**.
6. Choose **Enabled** within the **Turn On Virtualization Based Security** menu.
7. For **Select Platform Security Level**, choose **Secure Boot and DMA Protection**.
8. For **Credential Guard Configuration**, choose **Enabled with UEFI lock**.

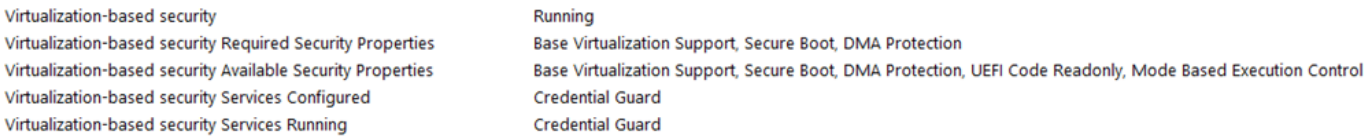
> **Note**
>
> The remaining policy settings are not required to enable Credential Guard and can be left as **Not Configured**.

The following image displays the VBS settings configured as described previously:

9. Reboot the instance to apply the settings.

Verify that Credential Guard is running

You can use the Microsoft System Information (`Msinfo32.exe`) tool to confirm that Credential Guard is running.



Important

You must first reboot the instance to finish applying the policy settings required to enable Credential Guard.

To verify Credential Guard is running

1. Connect to your instance using the Remote Desktop Protocol (RDP). For more information, see the section called "Connect using an RDP client".
2. Within the RDP session to your instance, open the Start menu and search for **cmd** to start a command prompt.
3. Open System Information by running the following command: `msinfo32.exe`
4. The Microsoft System Information tool lists the details for VBS configuration. Next to Virtualization-based security Services, confirm that **Credential Guard** appears as **Running**.

   The following image displays VBS is running as described previously:

Access Amazon EC2 using an interface VPC endpoint

You can improve the security posture of your VPC by creating a private connection between resources in your VPC and the Amazon EC2 API. You can access the Amazon EC2 API as if it were in your VPC, without the use of an internet gateway, NAT device, VPN connection, or Direct Connect connection. EC2 instances in your VPC don't need public IP addresses to access the Amazon EC2 API.

For more information, see Access AWS services through AWS PrivateLink in the *AWS PrivateLink Guide*.

Contents

- Create an interface VPC endpoint
- Create an endpoint policy

Create an interface VPC endpoint

Create an interface endpoint for Amazon EC2 using the following service name:

- **com.amazonaws.*region*.ec2** — Creates an endpoint for the Amazon EC2 API actions.

For more information, see Access an AWS service using an interface VPC endpoint in the *AWS PrivateLink Guide*.

Create an endpoint policy

An endpoint policy is an IAM resource that you can attach to your interface endpoint. The default endpoint policy allows full access to the Amazon EC2 API through the interface endpoint. To control the access allowed to the Amazon EC2 API from your VPC, attach a custom endpoint policy to the interface endpoint.

An endpoint policy specifies the following information:

- The principals that can perform actions.
- The actions that can be performed.
- The resource on which the actions can be performed.

> **Important**
>
> When a non-default policy is applied to an interface VPC endpoint for Amazon EC2, certain failed API requests, such as those failing from `RequestLimitExceeded`, might not be logged to AWS CloudTrail or Amazon CloudWatch.

For more information, see Control access to services using endpoint policies in the *AWS PrivateLink Guide*.

The following example shows a VPC endpoint policy that denies permission to create unencrypted volumes or to launch instances with unencrypted volumes. The example policy also grants permission to perform all other Amazon EC2 actions.

Storage options for your Amazon EC2 instances

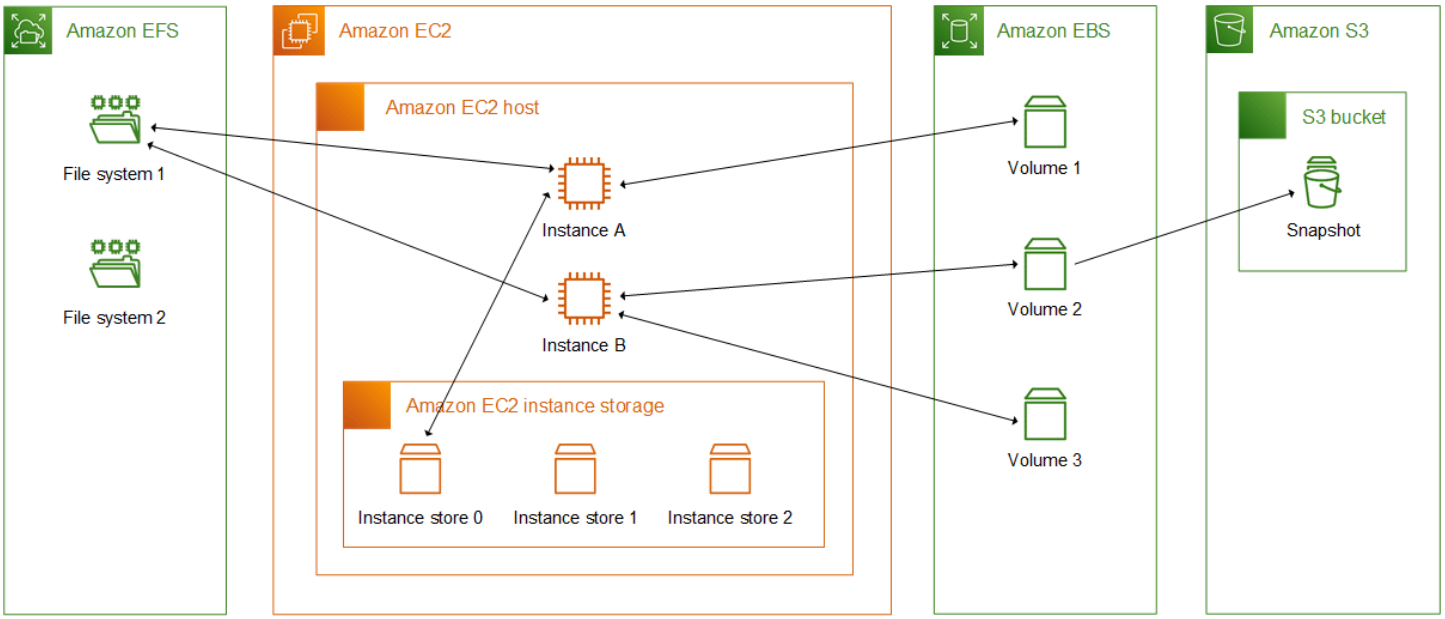
Amazon EC2 provides you with flexible, cost effective, and easy-to-use data storage options for your instances. Each option has a unique combination of performance and durability. These storage options can be used independently or in combination to suit your requirements.

Block storage

- Amazon EBS — Amazon EBS provides durable, block-level storage volumes that you can attach and detach from your instances. You can attach multiple EBS volumes to an instance. An EBS volume persists independently from the life of its associated instance. You can encrypt your EBS volumes. To keep a backup copy of your data, you can create snapshots from your EBS volumes. Snapshots are stored in Amazon S3. You can create an EBS volume from a snapshot.
- Instance store temporary block storage for EC2 instances — Instance store provides temporary block-level storage for instances. The number, size, and type of instance store volumes are determined by the instance type and instance size. The data on an instance store volume persists only during the life of the associated instance; if you stop, hibernate, or terminate an instance, any data on instance store volumes is lost.

Object storage

- Amazon S3 — Amazon S3 provides access to reliable and inexpensive data storage infrastructure. It is designed to make web-scale computing easier by enabling you to store and retrieve any amount of data, at any time, from within Amazon EC2 or anywhere on the web. For example, you can use Amazon S3 to store backup copies of your data and applications. Amazon EC2 uses Amazon S3 to store EBS snapshots and Amazon S3-backed AMIs.



File storage

- Amazon EFS (Linux instances only) — Amazon EFS provides scalable file storage for use with Amazon EC2. You can create an EFS file system and configure your instances to mount the file system. You can use an EFS file system as a common data source for workloads and applications running on multiple instances.
- Amazon FSx — With Amazon FSx, you can launch, run, and scale feature-rich, high-performance file systems in the cloud. Amazon FSx is a fully-managed service that supports a wide range of workloads. You can choose between these widely-used file systems: Lustre, NetApp ONTAP, OpenZFS, and Windows File Server.

File caching

- Use Amazon File Cache with Amazon EC2 instances — Amazon File Cache provides temporary, high-performance cache on AWS for processing file data. The cache provides read and write data access to compute workloads on Amazon EC2 with sub-millisecond latencies, up to hundreds of GB/s of throughput, and up to millions of IOPS.

The following figure shows the relationship between these storage options and your instance.

AWS Storage pricing

Open AWS Pricing, scroll to **Pricing for AWS products** and select **Storage**. Choose the storage product to open its pricing page.

Amazon EBS persistent block storage for Amazon EC2 instances

Amazon Elastic Block Store (Amazon EBS) provides scalable, high-performance block storage resources that can be used with Amazon EC2 instances. With Amazon EBS, you can create and manage the following block storage resources:

- **Amazon EBS volumes** — These are storage volumes that you attach to Amazon EC2 instances. After you attach a volume to an instance, you can use it in the same way you would use block storage. The instance can interact with the volume just as it would with a local drive.

- **Amazon EBS snapshots** — These are point-in-time backups of Amazon EBS volumes that persist independently from the volume itself. You can create snapshots to back up the data on your Amazon EBS volumes. You can then restore new volumes from those snapshots at any time.

You can create and attach EBS volumes to an instance during launch, and you can create and attach EBS volumes to an instance at any time after launch. You can also increase the size or performance of your EBS volumes without detaching the volume or restarting your instance.

You can create EBS snapshots from an EBS volume at any time after creation. You can use EBS snapshots to back up the data stored on your volumes. You can then use those snapshots to instantly restore volumes, or to migrate data across AWS accounts, AWS Regions, or Availability Zones. You can use Amazon Data Lifecycle Manager or AWS Backup to automate the creation, retention, and deletion of your EBS snapshots.

A *managed EBS volume* is managed by a service provider, such as Amazon EKS Auto Mode. You can't directly modify the settings of a managed EBS volume. Managed EBS volumes are identified by a **true** value in the **Managed** field. For more information, see Amazon EC2 managed instances.

For more information about working with volumes and snapshots, see the Amazon EBS User Guide.

Amazon EBS volume limits for Amazon EC2 instances

The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. If you exceed the volume attachment limit for an instance, the attachment request fails with the `AttachmentLimitExceeded` error.

When considering how many volumes to attach to your instance, you should consider whether you need increased I/O bandwidth or increased storage capacity.

Bandwidth versus capacity

For consistent and predictable bandwidth use cases, use Amazon EBS-optimized instances with General Purpose SSD volumes or Provisioned IOPS SSD volumes. For maximum performance, match the IOPS you have provisioned for your volumes with the bandwidth available for your instance type.

For RAID configurations, you might find that arrays larger than 8 volumes have diminished performance returns due to increased I/O overhead. Test your individual application performance and tune it as required.

  - Shared EBS volume limit
- Volume limits for Xen-based instances
  - Linux instances
  - Windows instances

Volume limits for instances built on the Nitro System

The volume limits for instances built on the Nitro System depend on the instance type. Some Nitro instance types have a **dedicated EBS volume limit**, while most have a **shared volume limit**. To view the volume attachment limits for each instance type, see the following:

- Amazon EBS specifications – General purpose
- Amazon EBS specifications – Compute optimized
- Amazon EBS specifications – Memory optimized
- Amazon EBS specifications – Storage optimized
- Amazon EBS specifications – Accelerated computing
- Amazon EBS specifications – High-performance computing
- Amazon EBS specifications – Previous generation

Dedicated EBS volume limit

The following Nitro instance types have a dedicated EBS volume limit that varies depending on instance size. The limit is not shared with other device attachments. In other words, you can attach any number of EBS volumes up to the volume attachment limit, regardless of the number of attached devices, such as NVMe instance store volumes and network interfaces.

- **General purpose:** M7a | M7i | M7i-flex | M8a | M8azn | M8g | M8gb | M8gd | M8gn | M8i | M8id | M8i-flex | M8in | M8idn | M8ine | M8ib | M8idb | M9g | M9gd | T8i
- **Compute optimized:** C7a | C7i | C7i-flex | C8a | C8g | C8gb | C8gd | C8gn | C8i | C8id | C8i-flex | C8in | C8ine | C8ib | C9g | C9gd

- **Memory optimized:** R7a | R7i | R7iz | R8a | R8g | R8gb | R8gd | R8gn | R8i | R8id | R8i-flex | R8in | R8idn | R8ib | R8idb | R9g | R9gd | U7i-6tb | U7i-8tb | U7i-12tb | U7in-16tb | U7in-24tb | U7in-32tb | U7inh-32tb | X8g | X8aedz | X8i
- **Storage optimized:** I7i | I7ie | I8g | I8ge
- **Accelerated computing:** F2 | G6 | G6e | G6f | Gr6 | Gr6f | G7 | G7e | P4d | P4de | P5 | P5e | P5en | P6-B200 | P6-B300 | P6e-GB200 | Trn2 | Trn2u
- **High performance computing:** Hpc7a | Hpc8a

Shared EBS volume limit

All other Nitro instance types (not listed in Dedicated EBS volume limit) have a volume attachment limit that is shared between Amazon EBS volumes, network interfaces, and NVMe instance store volumes. You can attach any number of Amazon EBS volumes up to that limit, less the number of attached network interfaces and NVMe instance store volumes. Keep in mind that every instance must have at least one network interface, and that NVMe instance store volumes are automatically attached at launch.

Most Nitro instances support a maximum of 28 attachments. The following examples demonstrate how to calculate how many EBS volumes you can attach.

Examples

- With an `m5.xlarge` instance with only the primary network interface, you can attach 27 EBS volumes.

  28 volumes - 1 network interface = 27
- With an `m5.xlarge` instance with two additional network interfaces, you can attach 25 EBS volumes.

  28 volumes - 3 network interfaces = 25
- With an `m5d.xlarge` instance with two additional network interfaces, you can attach 24 EBS volumes.

  28 volumes - 3 network interfaces - 1 NVMe instance store volume = 24

Volume limits for Xen-based instances

The volume limits for Xen-based instances, such as T2, depend on the operating system.

For more information, see Xen-based instances.

Linux instances

Attaching more than 40 volumes to a Xen-based Linux instance can cause boot failures. This number includes the root volume, plus any attached instance store volumes and Amazon EBS volumes.

If you experience boot problems on an instance with a large number of volumes, stop the instance, detach any volumes that are not essential to the boot process, start the instance, and then reattach the volumes after the instance is running.

> **Important**
>
> Attaching more than 40 volumes to a Xen-based Linux instance is supported on a best effort basis only and is not guaranteed.

Windows instances

The following table shows the volume limits for Xen-based Windows instances based on the driver used. That these numbers include the root volume, plus any attached instance store volumes and Amazon EBS volumes.

Driver	Volume Limit
AWS PV	26
Citrix PV	26
Red Hat PV	17

We recommend that you do not that attach more than 26 volumes to a Xen-based Windows instance with AWS PV or Citrix PV drivers, as it is likely to cause performance issues. To determine which PV drivers your instance is using, or to upgrade your Windows instance from Red Hat to Citrix PV drivers, see the section called “Upgrade PV drivers”.

Important

Attaching more than the following number of volumes to a Xen-based Windows instance is supported on a best effort basis only and is not guaranteed.

For more information about how device names are related to volumes, see How volumes are attached and mapped for Amazon EC2 Windows instances.

EBS cards

Most instance types support one EBS card. Instance types that support multiple EBS cards provide higher EBS-optimized performance, both in EBS throughput and IOPS. Your Amazon EC2 instance maximum performance is spread equally across each EBS card. For example, on an EC2 instance that supports `1,000,000` total IOPS with 2 EBS cards, each EBS card can support up to `500,000` IOPS. For information about the supported Amazon EBS performance of your Amazon EC2 instance, see Amazon EBS-optimized instance types.

When you attach an Amazon EBS volume to an instance that supports multiple EBS cards, you can select the EBS card for the volume by specifying the EBS card index. The root volume must be attached to EBS card index 0.

Instance types with multiple EBS cards

The following instance types support multiple EBS cards. For information about the number of Amazon EBS volumes that an instance type supports, see Amazon EBS volume limits for Amazon EC2 instances.

Instance Type	Number of EBS cards
General Purpose	
m8gb.48xlarge	2
m8gb.metal-48xl	2
m8gn.48xlarge	2
m8gn.metal-48xl	2

Instance Type	Number of EBS cards
m8in.96xlarge	2
m8in.metal-96xl	2
m8idn.96xlarge	2
m8idn.metal-96xl	2
m8ib.96xlarge	2
m8ib.metal-96xl	2
m8idb.96xlarge	2
m8idb.metal-96xl	2
Compute Optimized	
c8gb.48xlarge	2
c8gb.metal-48xl	2
c8gn.48xlarge	2

Instance store temporary block storage for EC2 instances

An *instance store* provides temporary block-level storage for your EC2 instance. This storage is provided by disks that are physically attached to the host computer. Instance store is ideal for temporary storage of information that changes frequently, such as buffers, caches, scratch data, and other temporary content. It can also be used to store temporary data that you replicate across a fleet of instances, such as a load-balanced pool of web servers.

An instance store consists of one or more instance store volumes exposed as block devices. The size of an instance store as well as the number of devices available varies by instance type and instance size. For example, not every instance type provides instance store volumes. For more information, see Instance store volume limits for EC2 instances.

The virtual devices for instance store volumes are given virtual device names in order from `ephemeral0` to `ephemeral23`. For example, with an instance type that supports one instance store volume, the virtual device name of the one volume is `ephemeral0`. With an instance type that supports four instance store volumes, the virtual device names of the four volumes are as follows: `ephemeral0`, `ephemeral1`, `ephemeral2` and `ephemeral3`.

Instance store pricing

There is no additional charge to use the instance store volumes provided for your instance. Instance store volumes are included as part of the usage cost of the instance.

Data persistence for Amazon EC2 instance store volumes

Instance store volumes are attached only at instance launch. You can't attach instance store volumes after launch. You can’t detach an instance store volume from one instance and attach it to a different instance.

An instance store volume exists only during the lifetime of the instance to which it is attached. You can’t configure an instance store volume to persist beyond the lifetime of its associated instance.

The data on an instance store volume persists even if the instance is rebooted. However, the data does not persist if the instance is stopped, hibernated, or terminated. When the instance is stopped, hibernated, or terminated, every block of the instance store volume is cryptographically erased.

Therefore, do not rely on instance store volumes for valuable, long-term data. If you need to retain the data stored on an instance store volume beyond the lifetime of the instance, you need to manually copy that data to more persistent storage, such as an Amazon EBS volume, an Amazon S3 bucket, or an Amazon EFS file system.

There are some events that can result in your data not persisting throughout the lifetime of the instance. The following table indicates whether data on instance store volumes is persisted during specific events, for both virtualized and bare metal instances.

Event	What happens to your data?
User-initiated instance lifecycle events	
The instance is rebooted	The data persists
The instance is stopped	The data does not persist
The instance is hibernated	The data does not persist
The instance is terminated	The data does not persist
The instance type is changed	The data does not persist *
An EBS-backed AMI is created from the instance	The data does not persist in the created AMI **

Event	What happens to your data?
An Amazon S3-backed AMI is created from the instance (Linux instances)	The data persists in the AMI bundle uploaded to Amazon S3 ***
User-initiated OS events	
A shutdown is initiated	The data does not persist †
A restart is initiated	The data persists
AWS scheduled events	
Instance stop	The data does not persist
Instance reboot	The data persists
System reboot	The data persists
Instance retirement	The data does not persist
Unplanned events	
Simplified automatic recovery	The data does not persist
CloudWatch action based recovery	The data does not persist
The underlying disk fails	The data on the failed disk does not persist
Power failure	The data persists upon reboot

* If the new instance type supports instance store, the instance gets the number of instance store volumes supported by the new instance type, but the data does not transfer to the new instance. If the new instance type does not support instance store, the instance does not get the instance store volumes.

** The data is not included in the EBS-backed AMI, and it is not included on instance store volumes attached to instances launched from that AMI.

*** The data is included in the AMI bundle that is uploaded to Amazon S3. When you launch an instance from that AMI, the instance gets the instance store volumes bundled in the AMI with the data they contained at the time the AMI was created.

† Termination protection and stop protection do not protect instances against instance stops or terminations as a result of shutdowns initiated through the operating system on the instance. Data stored on instance store volumes does not persist in both instance stop and termination events.

Instance store volume limits for EC2 instances

The number, size, and type of instance store volumes are determined by the instance type. Some instance types, such as C8i, M8i, and R8i, do not support instance store volumes, while other instance types, such as C8id, M8id, and R8id, do support instance store volumes. You can't attach more instance store volumes to an instance than is supported by its instance type. For the instance types that do support instance store volumes, the number and size of the instance store volumes vary by instance size. For example, `r8id.large` supports 1 x 118 GB instance store volume, while `r8id.32xlarge` supports 2 x 3800 GB instance store volumes.

For instance types with **NVMe instance store volumes**, all of the supported instance store volumes are automatically attached to the instance at launch. For instance types with **non-NVMe instance store volumes**, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, X1, and X1e, you must manually specify the block device mappings for the instance store volumes that you want to attach at launch. Then, after the instance has launched, you must format and mount the attached instance store volumes before you can use them. You can't attach an instance store volume after you launch the instance.

Some instance types use NVMe or SATA-based solid state drives (SSD), while others use SATA-based hard disk drives (HDD). SSDs deliver high random I/O performance with very low latency, but you don't need the data to persist when the instance terminates or you can take advantage of fault-tolerant architectures. For more information, see SSD instance store volumes for EC2 instances.

The data on NVMe instance store volumes and some HDD instance store volumes is encrypted at rest. For more information, see Data protection in Amazon EC2.

Available instance store volumes

The *Amazon EC2 Instance Types Guide* provides the quantity, size, type, and performance optimizations of instance store volumes available on each supported instance type. For more information, see the following:

- Instance store specifications – General purpose
- Instance store specifications – Compute optimized
- Instance store specifications – Memory optimized
- Instance store specifications – Storage optimized
- Instance store specifications – Accelerated computing
- Instance store specifications – High-performance computing
- Instance store specifications – Previous generation

Console

To retrieve instance store volume information

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instance Types**.
3. Add the filter **Local instance storage = true**. The **Storage** column indicates the total size of the instance storage for the instance type.
4. (Optional) Choose the **Preferences** icon and then turn on **Storage disk count**. This column indicates the number of instance store volumes.
5. (Optional) Add filters to further scope to specific instance types of interest.

AWS CLI

To retrieve instance store volume information

Use the describe-instance-types command. The following example displays the total size of the instance storage for each instance type in the R8i instance families with instance store volumes.

```
aws ec2 describe-instance-types \
    --filters "Name=instance-type,Values=r8i*" "Name=instance-storage-
supported,Values=true" \
    --query 'sort_by(InstanceTypes, &InstanceStorageInfo.TotalSizeInGB)[].
{InstanceType:InstanceType,TotalSizeInGB:InstanceStorageInfo.TotalSizeInGB}' \
    --output table
```

The following is example output.

```
-------------------------------------
```

```
|        DescribeInstanceTypes       |
+------------------+-----------------+
|   InstanceType   |  TotalSizeInGB  |
+------------------+-----------------+
|  r8id.large      |  118            |
|  r8id.xlarge     |  237            |
|  r8id.2xlarge    |  474            |
|  r8id.4xlarge    |  950            |
|  r8id.8xlarge    |  1900           |
|  r8id.12xlarge   |  2850           |
|  r8id.16xlarge   |  3800           |
|  r8id.24xlarge   |  5700           |
|  r8id.32xlarge   |  7600           |
|  r8id.48xlarge   |  11400          |
|  r8id.metal-48xl |  11400          |
|  r8id.96xlarge   |  22800          |
|  r8id.metal-96xl |  22800          |
+------------------+-----------------+
```

To get complete instance storage details for an instance type

Use the describe-instance-types command.

```
aws ec2 describe-instance-types \
    --filters "Name=instance-type,Values=r8id.32xlarge" \
    --query 'InstanceTypes[0].InstanceStorageInfo' \
    --output json
```

The example output shows that this instance type has two 3800 GB NVMe SSD volumes, for a total of 7600 GB of instance storage.

```
{
    "TotalSizeInGB": 7600,
    "Disks": [
        {
            "SizeInGB": 3800,
            "Count": 2,
            "Type": "ssd"
        }
    ],
    "NvmeSupport": "required",
    "EncryptionSupport": "required"
```

```
}
```

PowerShell

To retrieve instance store volume information

Use the Get-EC2InstanceType cmdlet. The following example displays the total size of the instance storage for each instance type in the R8i instance families with instance store volumes.

```
(Get-EC2InstanceType -Filter `
    @{Name="instance-type"; Values="r8i*"}, `
    @{Name="instance-storage-supported"; Values="true"}) |
    Sort-Object {$_.InstanceStorageInfo.TotalSizeInGB} |
    Format-Table InstanceType,

 @{Name="Disks.SizeInGB";Expression={$_.InstanceStorageInfo.Disks[0].SizeInGB}},
        @{Name="Disks.Count";Expression={$_.InstanceStorageInfo.Disks[0].Count}},
        @{Name="TotalSizeInGB";Expression={$_.InstanceStorageInfo.TotalSizeInGB}}
```

The following is example output.

```
InstanceType    Disks.SizeInGB Disks.Count TotalSizeInGB
------------    -------------- ----------- -------------
r8id.large                 118           1           118
r8id.xlarge                237           1           237
r8id.2xlarge               474           1           474
r8id.4xlarge               950           1           950
r8id.8xlarge              1900           1          1900
r8id.12xlarge             2850           1          2850
r8id.16xlarge             3800           1          3800
r8id.24xlarge             2850           2          5700
r8id.32xlarge             3800           2          7600
r8id.48xlarge             3800           3         11400
r8id.metal-48xl           3800           3         11400
r8id.96xlarge             3800           6         22800
r8id.metal-96xl           3800           6         22800
```

To get complete instance storage details for an instance type

Use the Get-EC2InstanceType cmdlet.

```
(Get-EC2InstanceType `
```

```
    -Filter @{Name="instance-type"; Values="r8id.32xlarge"}).InstanceStorageInfo |
    Format-List *,
        @{Name="Disks.Count";Expression={$_.Disks[0].Count}},
        @{Name="Disks.SizeInGB";Expression={$_.Disks[0].SizeInGB}},
        @{Name="Disks.Type";Expression={$_.Disks[0].Type.Value}}
```

The example output shows that this instance type has two 3800 GB NVMe SSD volumes, for a total of 7600 GB of instance storage.

```
Disks             : {Amazon.EC2.Model.DiskInfo}
EncryptionSupport : required
NvmeSupport       : required
TotalSizeInGB     : 7600
Disks.Count       : 2
Disks.SizeInGB    : 3800
Disks.Type        : ssd
```

SSD instance store volumes for EC2 instances

Like other instance store volumes, you must map the SSD instance store volumes for your instance when you launch it. The data on an SSD instance volume persists only for the life of its associated instance. For more information, see Add instance store volumes to an EC2 instance.

NVMe SSD volumes

Some instances offer non-volatile memory express (NVMe) solid state drives (SSD) instance store volumes. For more information about the type of instance store volume supported by each instance type, see Instance store volume limits for EC2 instances.

The data on NVMe instance storage is encrypted using an XTS-AES-256 block cipher implemented in a hardware module on the instance. The encryption keys are generated using the hardware module and are unique to each NVMe instance storage device. All encryption keys are destroyed when the instance is stopped or terminated and cannot be recovered. You cannot disable this encryption and you cannot provide your own encryption key.

Linux instances

To access NVMe volumes, the NVMe drivers must be installed. The following AMIs meet this requirement:

- AL2023
- Amazon Linux 2
- Amazon Linux AMI 2018.03 and later
- Ubuntu 14.04 or later with `linux-aws` kernel

> **Note**
>
> AWS Graviton-based instance types require Ubuntu 18.04 or later with `linux-aws` kernel

- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

- Bottlerocket

After you connect to your instance, you can list the NVMe devices using the **lspci** command. The following is example output for an `i3.8xlarge` instance, which supports four NVMe devices.

```
[ec2-user ~]$ lspci
00:00.0 Host bridge: Intel Corporation 440FX - 82441FX PMC [Natoma] (rev 02)
00:01.0 ISA bridge: Intel Corporation 82371SB PIIX3 ISA [Natoma/Triton II]
00:01.1 IDE interface: Intel Corporation 82371SB PIIX3 IDE [Natoma/Triton II]
00:01.3 Bridge: Intel Corporation 82371AB/EB/MB PIIX4 ACPI (rev 01)
00:02.0 VGA compatible controller: Cirrus Logic GD 5446
00:03.0 Ethernet controller: Device 1d0f:ec20
00:17.0 Non-Volatile memory controller: Device 1d0f:cd01
00:18.0 Non-Volatile memory controller: Device 1d0f:cd01
00:19.0 Non-Volatile memory controller: Device 1d0f:cd01
00:1a.0 Non-Volatile memory controller: Device 1d0f:cd01
00:1f.0 Unassigned class [ff80]: XenSource, Inc. Xen Platform Device (rev 01)
```

If you are using a supported operating system but you do not see the NVMe devices, verify that the NVMe module is loaded using the following command.

- Amazon Linux, Amazon Linux 2, Ubuntu 14/16, Red Hat Enterprise Linux, SUSE Linux Enterprise Server, CentOS 7

```
$ lsmod | grep nvme
nvme           48813  0
```

- Ubuntu 18

```
$ cat /lib/modules/$(uname -r)/modules.builtin | grep nvme
s/nvme/host/nvme-core.ko
kernel/drivers/nvme/host/nvme.ko
kernel/drivers/nvmem/nvmem_core.ko
```

The NVMe volumes are compliant with the NVMe 1.0e specification. You can use the NVMe commands with your NVMe volumes. With Amazon Linux, you can install the `nvme-cli` package from the repo using the **yum install** command. With other supported versions of Linux, you can download the `nvme-cli` package if it's not available in the image.

Windows instances

The latest AWS Windows AMIs for the following operating systems contain the AWS NVMe drivers used to interact with SSD instance store volumes that are exposed as NVMe block devices for better performance:

- Windows Server 2025
- Windows Server 2022
- Windows Server 2019
- Windows Server 2016
- Windows Server 2012 R2

After you connect to your instance, you can verify that you see the NVMe volumes in Disk Manager. On the taskbar, open the context (right-click) menu for the Windows logo and choose **Disk Management**.

The AWS Windows AMIs provided by Amazon include the AWS NVMe driver. If you are not using the latest AWS Windows AMIs, you can install the current AWS NVMe driver.

Non-NVMe SSD volumes

The following instances support instance store volumes that use non-NVMe SSDs to deliver high random I/O performance: C3, I2, M3, R3, and X1. For more information about the instance store volumes supported by each instance type, see Instance store volume limits for EC2 instances.

SSD-based instance store volume I/O performance

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called *over-provisioning*. The SSD-based instance store volumes provided to an instance do not have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10 percent of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you have written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see Instance store volume TRIM support.

Instance store volume TRIM support

Some instance types support SSD volumes with TRIM. For more information, see Instance store volume limits for EC2 instances.

> **Note**
>
> (Windows instances only) Instances running Windows Server 2012 R2 support TRIM as of AWS PV Driver version 7.3.0. Instances running earlier versions of Windows Server do not support TRIM.

Instance store volumes that support TRIM are fully trimmed before they are allocated to your instance. These volumes are not formatted with a file system when an instance launches, so you must format them before they can be mounted and used. For faster access to these volumes, you should skip the TRIM operation when you format them.

(Windows instances) To temporarily disable TRIM support during initial formatting, use the `fsutil behavior set DisableDeleteNotify 1` command. After formatting is complete, re-enable TRIM support by using `fsutil behavior set DisableDeleteNotify 0`.

With instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller when you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. On **Linux instances**, use the `fstrim` command to enable periodic TRIM. On **Windows instances**, use the `fsutil behavior set DisableDeleteNotify 0` command to ensure TRIM support is enabled during normal operation.

Add instance store volumes to an EC2 instance

For instance types with **NVMe instance store volumes**, all of the supported instance store volumes are automatically attached to the instance at launch. They are automatically enumerated and assigned a device name on instance launch.

For instance types with **non-NVMe instance store volumes**, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, X1, and X1e, you must manually specify the block device mappings for the instance store volumes that you want to attach at launch. Block device mappings can be specified in the instance launch request or in the AMI used to launch the instance. The block device mapping includes a device name and the volume that it maps to. For more information, see Block device mappings for volumes on Amazon EC2 instances

> **Important**
>
> Instance store volumes can be attached to an instance only when you launch it. You can't attach instance store volumes to an instance after you've launched it.

After you launch an instance, you must ensure that the instance store volumes for your instance are formatted and mounted before you can use them. The instance store root volume is mounted automatically.

Consideration for root volumes

A block device mapping always specifies the root volume for the instance. The root volume is always mounted automatically.

Linux instances – The root volume is either an Amazon EBS volume or an instance store volume. For instances with an instance store volume for the root volume, the size of this volume varies by AMI, but the maximum size is 10 GB. For more information, see Root volume type.

Windows instances – The root volume must be an Amazon EBS volume. Instance store is not supported for the root volume.

Contents

- Add instance store volumes to an Amazon EC2 AMI
- Add instance store volumes to an EC2 instance during launch
- Make instance store volume available for use on an EC2 instance

Add instance store volumes to an Amazon EC2 AMI

You can create an AMI with a block device mapping that includes instance store volumes.

If you launch an instance that supports **non-NVMe instance store volumes** using an AMI that specifies instance store volume block device mappings, the instance includes the instance store volumes. If the number of instance store volume block device mappings in the AMI exceeds the number of instance store volumes available to the instance, the additional instance store volume block device mappings are ignored.

If you launch an instance that supports **NVMe instance store volumes** using an AMI that specifies instance store volume block device mappings, the instance store volume block device mappings are

ignored. Instances that support NVMe instance store volumes get all of their supported instance store volumes, regardless of the block device mappings specified in the instance launch request and the AMI. The device mapping of these volumes depends on the order in which the operating system enumerates the volumes.

Considerations

- The number of available instance store volumes depends on the instance type. For more information, see the section called “Available instance store volumes”.
- You must specify a device name for each block device. For more information, see Device names for volumes on Amazon EC2 instances.
- When you launch an instance, you can omit non-NVMe instance store volumes specified in the AMI block device mapping or add instance store volumes.
- For M3 instances, specify instance store volumes in the block device mapping of the instance, not the AMI. Amazon EC2 might ignore instance store volume block device mappings in the AMI.

Console

To add instance store volumes to an Amazon EBS-backed AMI

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances** and select the instance.
3. Choose **Actions**, **Image and templates**, **Create image**.
4. On the **Create image** page, enter a meaningful name and description for your image.
5. For each instance store volume to add, choose **Add volume**, from **Volume type** select an instance store volume, and from **Device** select a device name.
6. Choose **Create image**.

AWS CLI

To add instance store volumes to an AMI

Use the create-image command with the `--block-device-mappings` option to specify a block device mapping for an EBS-backed AMI. Use the register-image command with the `--block-device-mappings` option to specify a block device mapping for an iAmazon S3-backed AMI.

```
--block-device-mappings file://mapping.json
```

The following block device mapping adds two instance store volumes.

```
[
    {
        "DeviceName": "/dev/sdc",
        "VirtualName": "ephemeral0"
    },
    {
        "DeviceName": "/dev/sdd",
        "VirtualName": "ephemeral1"
    }
]
```

PowerShell

To add instance store volumes to an AMI

Use the New-EC2Image cmdlet with the `-BlockDeviceMapping` parameter to specify a block device mapping for an EBS-backed AMI. Use the Register-EC2Image cmdlet with the `-BlockDeviceMapping` parameter to specify a block device mapping for an Amazon S3-backed AMI.

```
-BlockDeviceMapping $bdm
```

The following block device mapping adds two instance store volumes.

```
$bdm = @()

$sdc = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdc.DeviceName = "/dev/sdc"
$sdc.VirtualName = "ephemeral0"
$bdm += $sdc

$sdd = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdd.DeviceName = "/dev/sdd"
$sdd.VirtualName = "ephemeral1"
$bdm += $sdd
```

Add instance store volumes to an EC2 instance during launch

When you launch an instance type with **non-NVMe instance store volumes**, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, X1, and X1e, you must specify the block device mappings for the instance store volumes that you want to attach at launch. The block device mappings must be specified in the instance launch request or in the AMI used to launch the instance.

If the AMI includes block device mappings for the instance store volumes, you do not need to specify block device mappings in the instance launch request, unless you need more instance store volumes than is included in the AMI.

If the AMI does not include block device mappings for instance store volumes, then you must specify the block device mappings in the instance launch request.

For instance types with NVMe instance store volumes, all of the supported instance store volumes are automatically attached to the instance at launch.

Considerations

- The number of available instance store volumes depends on the instance type. For more information, see the section called “Available instance store volumes”.
- You must specify a device name for each block device. For more information, see Device names for volumes on Amazon EC2 instances.
- For M3 instances, you might receive instance store volumes even if you do not specify them in the block device mapping for the instance.

Console

To specify a block device mapping in an instance launch request

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. From the dashboard, choose **Launch instance**.
3. In the **Application and OS Images** section, select the AMI to use.
4. In the **Configure storage** section, the **Instance store volumes** section lists the instance store volumes that can be attached to the instance.
5. For each instance store volume to attach, for **Device name**, select the device name to use.
6. Configure the remaining instance settings as needed, and then choose **Launch instance**.

AWS CLI

To specify a block device mapping in an instance launch request

Use the run-instances command with the `--block-device-mappings` option.

```
--block-device-mappings file://mapping.json
```

The following block device mapping adds two instance store volumes.

```
[
    {
        "DeviceName": "/dev/sdc",
        "VirtualName": "ephemeral0"
    },
    {
        "DeviceName": "/dev/sdd",
        "VirtualName": "ephemeral1"
    }
]
```

PowerShell

To specify a block device mapping in an instance launch request

Use the New-EC2Instance cmdlet with the `-BlockDeviceMapping` option.

```
-BlockDeviceMapping $bdm
```

The following block device mapping adds two instance store volumes.

```
$bdm = @()

$sdc = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdc.DeviceName = "/dev/sdc"
$sdc.VirtualName = "ephemeral0"
$bdm += $sdc

$sdd = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdd.DeviceName = "/dev/sdd"
$sdd.VirtualName = "ephemeral1"
$bdm += $sdd
```

Make instance store volume available for use on an EC2 instance

After you launch an instance with attached instance store volumes, you must mount the volumes before you can access them.

Linux instances

You can format volumes with the file system of your choice after you launch your instance.

To make an instance store volume available on Linux

1. Connect to the instance using an SSH client. For more information, see Connect to your Linux instance using SSH.
2. Use the `df -h` command to view the volumes that are formatted and mounted.

```
$ df -h
Filesystem      Size  Used Avail Use% Mounted on
devtmpfs        3.8G   72K  3.8G   1% /dev
tmpfs           3.8G     0  3.8G   0% /dev/shm
/dev/nvme0n1p1  7.9G  1.2G  6.6G  15% /
```

3. Use the `lsblk` to view any volumes that were mapped at launch but not formatted and mounted.

```
$ lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
nvme0n1       259:1    0    8G  0 disk
##nvme0n1p1   259:2    0    8G  0 part /
##nvme0n1p128 259:3    0    1M  0 part
nvme1n1       259:0    0 69.9G  0 disk
```

4. To format and mount an instance store volume that was mapped only, do the following:

   a. Create a file system on the device using the `mkfs` command.

   ```
   $ sudo mkfs -t xfs /dev/nvme1n1
   ```

   b. Create a directory on which to mount the device using the `mkdir` command.

   ```
   $ sudo mkdir /data
   ```

   c. Mount the device on the newly created directory using the `mount` command.

```
$ sudo mount /dev/nvme1n1 /data
```

Windows instances

For Windows instances, we reformat the instance store volumes with the NTFS file system.

You can view the instance store volumes using Windows Disk Management. For more information, see List non-NVMe disks.

To manually mount an instance store volume

1. Choose **Start**, enter **Computer Management**, and then press **Enter**.
2. In left-hand panel, choose **Disk Management**.
3. If you are prompted to initialize the volume, choose the volume to initialize, select the required partition type depending on your use case, and then choose **OK**.
4. In the list of volumes, open the context (right-click) menu for the volume to mount, and then choose **New Simple Volume**.
5. On the wizard, choose **Next**.
6. On the Specify Volume Size screen, choose **Next** to use the maximum volume size. Alternatively, choose a volume size that is between the minimum and maximum disk space.
7. On the Assign a Drive Letter or Path screen, do one of the following, and choose **Next**.
   - To mount the volume with a drive letter, choose **Assign the following drive letter** and then choose the drive letter to use.
   - To mount the volume as a folder, choose **Mount in the following empty NTFS folder** and then choose **Browse** to create or select the folder to use.
   - To mount the volume without a drive letter or path, choose **Do not assign a drive letter or drive path**.
8. On the Format Partition screen, specify whether to format the volume. If you choose to format the volume, choose the required file system and unit size, and specify a volume label.
9. Choose **Next**, **Finish**.

Enable instance store swap volume for M1 and C1 EC2 instances

> **Note**
>
> This topic applies to `c1.medium` and `m1.small` Linux instances only.

The `c1.medium` and `m1.small` instance types have a limited amount of physical memory. Therefore, they are given a 900 MiB swap volume at launch time to act as virtual memory, or *swap space*, for the Linux system. Swap space in Linux can be used when a system requires more memory than it has been physically allocated. When swap space is enabled, Linux systems can swap infrequently used memory pages from physical memory to swap space (either a dedicated partition or a swap file in an existing file system) and free up that space for memory pages that require high-speed access.

> **Note**
>
> - Using swap space for memory paging is not as fast or efficient as using RAM. If your workload is regularly paging memory into swap space, you should consider migrating to a larger instance type with more RAM. For more information, see Amazon EC2 instance type changes.
> - Although the Linux kernel sees this swap space as a partition on the root volume, it is actually a separate instance store volume, regardless of your root volume type.

Amazon Linux automatically enables and uses this swap space, but your AMI may require some additional steps to recognize and use this swap space. To see if your instance is using swap space, you can use the **swapon -s** command.

```
[ec2-user ~]$ swapon -s
Filename                                Type            Size    Used    Priority
/dev/xvda3                              partition       917500  0       -1
```

The above instance has a 900 MiB swap volume attached and enabled. If you don't see a swap volume listed with this command, you may need to enable swap space for the device. Check your available disks using the **lsblk** command.

```
[ec2-user ~]$ lsblk
```

```
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda1 202:1    0    8G  0 disk /
xvda3 202:3    0  896M  0 disk
```

Here, the swap volume `xvda3` is available to the instance, but it is not enabled (notice that the `MOUNTPOINT` field is empty). You can enable the swap volume with the **swapon** command.

> **Note**
>
> You must prepend `/dev/` to the device name listed by **lsblk**. Your device may be named differently, such as `sda3`, `sde3`, or `xvde3`. Use the device name for your system in the command below.

```
[ec2-user ~]$ sudo swapon /dev/xvda3
```

Now the swap space should show up in **lsblk** and **swapon -s** output.

```
[ec2-user ~]$ lsblk
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda1 202:1    0    8G  0 disk /
xvda3 202:3    0  896M  0 disk [SWAP]
[ec2-user ~]$ swapon -s
Filename                                Type            Size    Used    Priority
/dev/xvda3                              partition       917500  0       -1
```

You also need to edit your `/etc/fstab` file so that this swap space is automatically enabled at every system boot.

```
[ec2-user ~]$ sudo vim /etc/fstab
```

Append the following line to your `/etc/fstab` file (using the swap device name for your system):

```
/dev/xvda3       none    swap    sw  0       0
```

To use an instance store volume as swap space

Any instance store volume can be used as swap space. For example, the `m3.medium` instance type includes a 4 GB SSD instance store volume that is appropriate for swap space. If your instance store

volume is much larger (for example, 350 GB), you may consider partitioning the volume with a smaller swap partition of 4-8 GB and the rest for a data volume.

> **Note**
>
> This procedure applies only to instance types that support instance storage. For a list of supported instance types, see Instance store volume limits for EC2 instances.

1. List the block devices attached to your instance to get the device name for your instance store volume.

```
[ec2-user ~]$ lsblk -p
NAME       MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
/dev/xvdb  202:16   0   4G  0 disk /media/ephemeral0
/dev/xvda1 202:1    0   8G  0 disk /
```

   In this example, the instance store volume is `/dev/xvdb`. Because this is an Amazon Linux instance, the instance store volume is formatted and mounted at `/media/ephemeral0`; not all Linux operating systems do this automatically.

2. (Optional) If your instance store volume is mounted (it lists a `MOUNTPOINT` in the **lsblk** command output), unmount it with the following command.

```
[ec2-user ~]$ sudo umount /dev/xvdb
```

3. Set up a Linux swap area on the device with the **mkswap** command.

```
[ec2-user ~]$ sudo mkswap /dev/xvdb
mkswap: /dev/xvdb: warning: wiping old ext3 signature.
Setting up swapspace version 1, size = 4188668 KiB
no label, UUID=b4f63d28-67ed-46f0-b5e5-6928319e620b
```

4. Enable the new swap space.

```
[ec2-user ~]$ sudo swapon /dev/xvdb
```

5. Verify that the new swap space is being used.

```
[ec2-user ~]$ swapon -s
```

```
Filename    Type  Size Used Priority
/dev/xvdb                              partition 4188668 0 -1
```

6. Edit your `/etc/fstab` file so that this swap space is automatically enabled at every system boot.

```
[ec2-user ~]$ sudo vim /etc/fstab
```

If your `/etc/fstab` file has an entry for `/dev/xvdb` (or `/dev/sdb`) change it to match the line below; if it does not have an entry for this device, append the following line to your `/etc/fstab` file (using the swap device name for your system):

```
/dev/xvdb       none    swap    sw  0       0
```

> **Important**
>
> Instance store volume data is lost when an instance is stopped or hibernated; this includes the instance store swap space formatting created in Step 3. If you stop and restart an instance that has been configured to use instance store swap space, you must repeat Step 1 through Step 5 on the new instance store volume.

Initialize instance store volumes on EC2 instances

Because of the way that Amazon EC2 virtualizes disks, the first write to any location on some instance store volumes performs more slowly than subsequent writes. For most applications, amortizing this cost over the lifetime of the instance is acceptable. However, if you require high disk performance, we recommend that you initialize your drives by writing once to every drive location before production use.

> **Note**
>
> Instance types with direct-attached solid state drives (SSD) and TRIM support provide maximum performance at launch time, without initialization. For information about the instance store for each instance type, see Instance store volume limits for EC2 instances.

If you require greater flexibility in latency or throughput, we recommend using Amazon EBS.

To initialize the instance store volumes, use the following dd commands, depending on the store to initialize (for example, `/dev/sdb` or `/dev/nvme1n1`).

> **Note**
>
> Make sure to unmount the drive before performing this command.
> Initialization can take a long time (about 8 hours for an extra large instance).

To initialize the instance store volumes, use the following commands on the `m1.large`, `m1.xlarge`, `c1.xlarge`, `m2.xlarge`, `m2.2xlarge`, and `m2.4xlarge` instance types:

```
dd if=/dev/zero of=/dev/sdb bs=1M
dd if=/dev/zero of=/dev/sdc bs=1M
dd if=/dev/zero of=/dev/sdd bs=1M
dd if=/dev/zero of=/dev/sde bs=1M
```

To perform initialization on all instance store volumes at the same time, use the following command:

```
dd if=/dev/zero bs=1M|tee /dev/sdb|tee /dev/sdc|tee /dev/sde > /dev/sdd
```

Configuring drives for RAID initializes them by writing to every drive location. When configuring software-based RAID, make sure to change the minimum reconstruction speed:

```
echo $((30*1024)) > /proc/sys/dev/raid/speed_limit_min
```

Detailed performance statistics for Amazon EC2 instance store volumes

Amazon EC2 provides real-time, high-resolution performance statistics for NVMe instance store volumes attached to Nitro-based Amazon EC2 instances. These statistics are presented as aggregated counters that are retained for the duration of the instance's lifetime. The statistics provide details about the cumulative number of operations, bytes sent and received, time spent on read and write I/O operations, and histograms for read and write I/O operations. While these statistics maintain consistency with Amazon EBS detailed performance statistics, they also include detailed latency histograms broken down by I/O size, which can provide more granular insights into your storage performance patterns. This enhanced visibility enables you to precisely identify

which specific I/O sizes are experiencing latency issues, allowing you to optimize application performance and troubleshoot issues more effectively.

You can collect these statistics at a granularity of up to 1 second intervals. If requests are made more frequently than 1 second intervals, the NVMe driver might queue the requests, along with other admin commands, to be processed at a later time.

Considerations

- The statistics are supported only for NVMe instance store volumes attached to Nitro-based instances.
- The counters are not persistent across instance stops and restarts.
- The statistics are available at no additional cost.

Statistics

The NVMe block device vends the following statistics:

Statistic name	Full name	Type	Description
`total_rea d_ops`	Total read operations	Counter	The total number of completed read operation s.
`total_wr te_ops`	Total write operation s	Counter	The total number of completed write operations.
`total_rea d_bytes`	Total read bytes	Counter	The total number of read bytes transferred.
`total_wr te_bytes`	Total write bytes	Counter	The total number of write bytes transferred.
`total_rea d_time`	Total read time	Counter	The total time spent, in microseconds, by all completed read operations.
`total_wr te_time`	Total write time	Counter	The total time spent, in microseconds, by all completed write operations.

Statistic name	Full name	Type	Description
instance_store_volume_performance_exceeded_iops	Total time demand exceeded volume's maximum IOPS	Counter	The total time, in microseconds, that IOPS requests exceeded the volume's maximum IOPS. Any value above 0 indicates that your workload demanded more IOPS than the volume could deliver. Ideally, the incremental count of this metric, between two snapshot times, should be minimal.
instance_store_volume_performance_exceeded_tp	Total time demand exceeded volume's maximum throughput	Counter	The total time, in microseconds, that throughput requests exceeded the volume's maximum throughput. Any value above 0 indicates that your workload demanded more throughput than the volume could deliver. Ideally, the incremental count of this metric, between two snapshot times, should be minimal.
volume_queue_length	Volume queue length	Point in time	The number of read and write operations waiting to be completed.
read_io_latency_histogram	Read I/O histogram	Histogram *	The number of read operations completed within each latency bin, in microseconds.
write_io_latency_histogram	Write I/O histogram	Histogram *	The number of write operations completed within each latency bin, in microseconds.

Note

* Histogram statistics represent only I/O operations that have completed successfully. Stalled or impaired I/O operations are not included, but will be evident in the `volume_queue_length` statistics, which is presented as a point-in-time statistic.

Accessing the statistics

The statistics must be accessed directly from the instance to which the instance store volumes is attached. You can access the statistics using one of the following methods.

Linux instances

Amazon CloudWatch

You can configure the Amazon CloudWatch agent to collect the statistics from your instance and make them available as custom metrics in CloudWatch. You can then use the metrics in CloudWatch to analyze I/O patterns, track performance trends, create custom dashboards, and set up automated alarms based on performance thresholds.

For more information about configuring the CloudWatch agent, see Collect Amazon EC2 instance store volume metrics.

nvme-cli tool

To access the statistics

1. Connect to the instance to which the volume is attached.
2. Amazon Linux 2023 AMIs released after September 15, 2025 include the latest version of the `nvme-cli` tool. If you are using an older Amazon Linux AMI, update the `nvme-cli` tool.

```
sudo yum install nvme-cli
```

3. Run the following command and specify the device name for the volume.

```
sudo nvme amzn stats /dev/nvme0n1
```

The statistics also provide detailed latency histograms broken down by I/O size. To view statistics broken down by I/O size, include the `--details` option. For example:

```
sudo nvme amzn stats --details /dev/nvme0n1
```

You can get more information about how to use the tool by specifying the `--help` option. For example:

```
sudo nvme amzn stats --help
```

Windows instances

nvme_amzn.exe tool

To access the statistics

1. Connect to the instance to which the volume is attached.
2. Make sure that you're using AWSNVMe driver version `1.7.0` or later. For more information about updating the AWSNVMe driver, see AWS NVMe drivers.
3. Get the disk number for the volume. For more information, see Map NVMe disks on Amazon EC2 Windows instance to volumes.
4. Run the following command as Administrator and specify the disk number for the volume.

   ```
   .\nvme_amzn.exe stats disk_number
   ```

The statistics also provide detailed latency histograms broken down by I/O size. To view statistics broken down by I/O size, include the `--details` option. For example:

```
.\nvme_amzn.exe stats --details disk_number
```

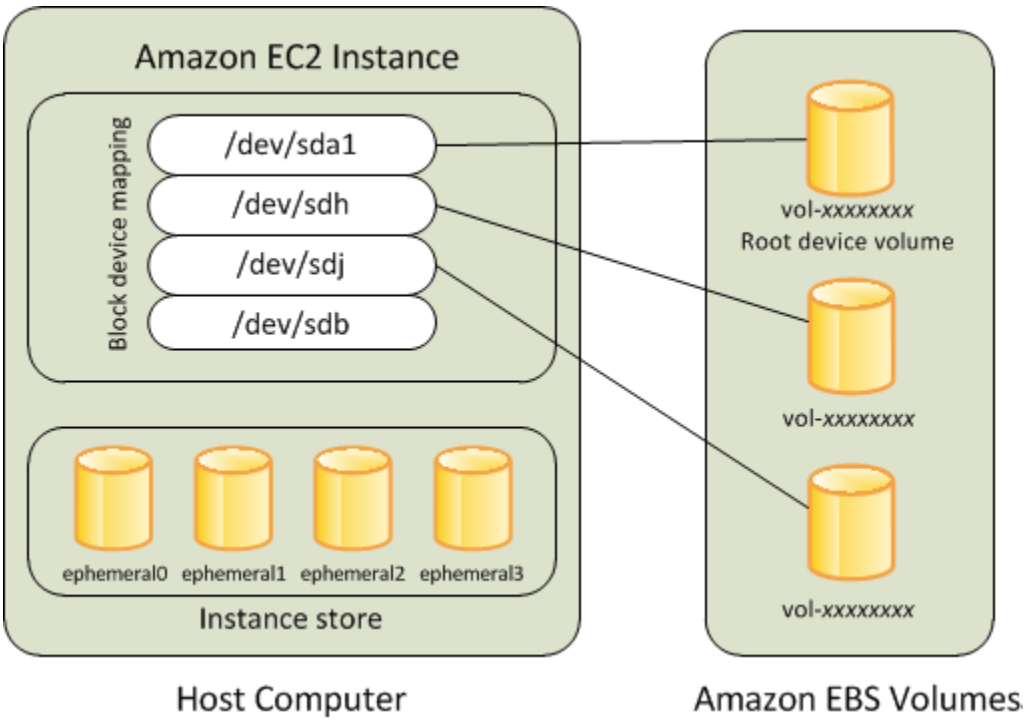
Root volumes for your Amazon EC2 instances

When you launch an instance, we create a *root volume* for the instance. The root volume contains the image used to boot the instance. Each instance has a single root volume. You can add storage volumes to your instances during or after launch.

The AMI that you use to launch an instance determines the type of root volume. You can launch an instance from either an *Amazon EBS-backed AMI* (Linux and Windows instances) or an *Amazon S3-backed AMI* (Linux instances only). There are significant differences between what you can do with each type of AMI. For more information about these differences, see Root volume type.

We recommend that you use AMIs backed by Amazon EBS, because these instances launch faster and use persistent storage.

We reserve specific device names for root volumes. For more information, see Device names for volumes on Amazon EC2 instances.



Contents

- Instances with an Amazon EBS root volume
- Instances with an instance store root volume (Linux instances only)
- Keep an Amazon EBS root volume after an Amazon EC2 instance terminates
- Replace the root volume for an Amazon EC2 instance without stopping it

Instances with an Amazon EBS root volume

Instances that use Amazon EBS for the root volume automatically have an Amazon EBS volume attached. When you launch an instance with an Amazon EBS-AMI, we create an Amazon EBS volume for each Amazon EBS snapshot referenced by the AMI. You can optionally use other Amazon EBS volumes or instance store volumes, depending on the instance type.

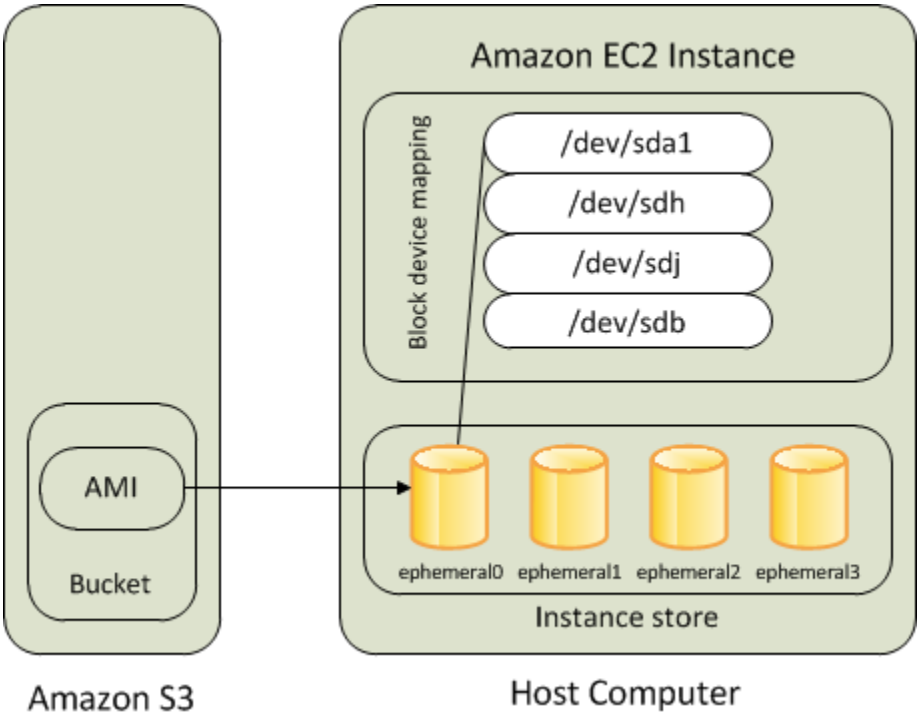
An instance with an EBS root volume can be stopped and later restarted without affecting data stored in the attached volumes. There are various instance– and volume-related tasks you can do when an instance with an EBS root volume is in a stopped state. For example, you can modify the properties of the instance, change its size, or update the kernel it is using, or you can attach its root volume to a different running instance for debugging or any other purpose. For more information, see Amazon EBS volumes.

Limitation

You can't use `st1` or `sc1` EBS volumes as root volumes.

Instance failure

If an instance with an EBS root volume fails, you can restore your session by following one of these methods:



- Stop and then start again (try this method first).
- Automatically snapshot all relevant volumes and create a new AMI. For more information, see Create an Amazon EBS-backed AMI.
- Attach the volume to the new instance by following these steps:
  1. Create a snapshot of the root volume.
  2. Register a new AMI using the snapshot.
  3. Launch a new instance from the new AMI.
  4. Detach the remaining Amazon EBS volumes from the old instance.
  5. Reattach the Amazon EBS volumes to the new instance.

Instances with an instance store root volume (Linux instances only)

> **Note**
>
> Windows instances do not support instance store root volumes.

Instances that use instance store for the root volume automatically have one or more instance store volumes available, with one volume serving as the root volume. When an instance is launched from an Amazon S3-backed AMI, the AMI is copied to the root volume. Note that you can optionally use additional instance store volumes, depending on the instance type.

Any data on the instance store volumes persists as long as the instance is running, but this data is deleted when the instance is terminated (instances with an instance store root volume do not support the **Stop** action) or if it fails (such as if an underlying drive has issues). For more information, see Instance store temporary block storage for EC2 instances.

Supported instance types

Only the following instance types support an instance store volume as the root volume: C1, C3, D2, I2, M1, M2, M3, R3, and X1.

Instance failure

After an instance with an instance store root volume fails or terminates, it can't be restored. If you plan to use an instances with an instance store root volume, we highly recommend that you distribute the data on your instance store volumes across multiple Availability Zones. You should also back up critical data from your instance store volumes to persistent storage on a regular basis.

Keep an Amazon EBS root volume after an Amazon EC2 instance terminates

By default, the Amazon EBS root volume for an instance is deleted when the instance terminates. You can change the default behavior to ensure that an Amazon EBS root volume persists after the instance terminates. To change the default behavior, set the `DeleteOnTermination` attribute to `false`. You can do so either at instance launch or later on.

Tasks

- Configure the root volume to persist during instance launch
- Configure the root volume to persist for an existing instance
- Confirm that a root volume is configured to persist

Configure the root volume to persist during instance launch

You can configure the root volume to persist when you launch an instance.

Console

To configure the root volume to persist when you launch an instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances** and then choose **Launch instances**.
3. Choose an Amazon Machine Image (AMI), choose and instance type, choose a key pair, and configure your network settings.
4. For **Configure storage**, choose **Advanced**.
5. Expand the root volume.
6. For **Delete on termination**, choose **No**.
7. When you are finished configuring your instance, choose **Launch instance**.

AWS CLI

To configure the root volume to persist when you launch an instance

Use the run-instances command and include the following option.

```
--block-device-mappings file://mapping.json
```

In `mapping.json`, specify a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```
[
    {
        "DeviceName": "/dev/sda1",
        "Ebs": {
            "DeleteOnTermination": false
        }
    }
]
```

PowerShell

To configure the root volume to persist when you launch an instance

Use the New-EC2Instance cmdlet and include the following parameter.

```
-BlockDeviceMapping $bdm
```

Create a block device mapping that sets the `DeleteOnTermination` attribute to `$false`.

```
$ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
$ebs.DeleteOnTermination = $false
$bdm = New-Object Amazon.EC2.Model.BlockDeviceMapping
$bdm.DeviceName = "dev/xvda"
$bdm.Ebs = $ebs
```

Configure the root volume to persist for an existing instance

You can configure the root volume to persist for a running instance. Note that you can't complete this task using the Amazon EC2 console.

AWS CLI

To configure the root volume to persist for an existing instance

Use the modify-instance-attribute command with a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --block-device-mappings file://mapping.json
```

Specify the following in `mapping.json`.

```
[
    {
        "DeviceName": "/dev/xvda",
        "Ebs": {
            "DeleteOnTermination": false
        }
    }
]
```

PowerShell

To configure the root volume to persist for an existing instance

Use the Edit-EC2InstanceAttribute cmdlet with a block device mapping that sets the `DeleteOnTermination` attribute to `$false`.

```
$ebs = New-Object Amazon.EC2.Model.EbsInstanceBlockDeviceSpecification
$ebs.DeleteOnTermination = $false
$bdm = New-Object Amazon.EC2.Model.InstanceBlockDeviceMappingSpecification
$bdm.DeviceName = "/dev/xvda"
$bdm.Ebs = $ebs
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -BlockDeviceMapping $bdm
```

Confirm that a root volume is configured to persist

You can confirm that a root volume is configured to persist.

Console

To confirm that a root volume is configured to persist

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances** and then select the instance.
3. In the **Storage** tab, under **Block devices**, locate the entry for the root volume. If **Delete on termination** is No, the volume is configured to persist.

AWS CLI

To confirm that a root volume is configured to persist

Use the describe-instances command and verify that the `DeleteOnTermination` attribute is set to `false`.

```
aws ec2 describe-instances \
    --instance-id i-1234567890abcdef0 \
    --query "Reservations[].Instances[].BlockDeviceMappings"
```

The following is example output.

```
[
    [
        {
            "DeviceName": "/dev/xvda",
            "Ebs": {
                "AttachTime": "2024-07-12T04:05:33.000Z",
                "DeleteOnTermination": false,
                "Status": "attached",
                "VolumeId": "vol-1234567890abcdef0"

        }
    ]
]
```

PowerShell

To confirm that a root volume is configured to persist

Use the Get-EC2Instance cmdlet and verify that the `DeleteOnTermination` attribute is set to `False`.

```
(Get-EC2Instance -InstanceId i-
i-1234567890abcdef0).Instances.BlockDeviceMappings.Ebs
```

The following is example output.

```
AssociatedResource  :
AttachTime          : 7/12/2024 4:05:33 AM
DeleteOnTermination : False
Operator            :
Status              : attached
VolumeId            : vol-1234567890abcdef0
```

Replace the root volume for an Amazon EC2 instance without stopping it

Amazon EC2 enables you to replace the root Amazon EBS volume for a running instance while retaining the following:

- Data stored on instance store volumes — Instance store volumes remain attached to the instance after the root volume has been restored.
- Data stored on data (non-root) Amazon EBS volumes — Non-root Amazon EBS volumes remain attached to the instance after the root volume has been restored.
- Network configuration — All network interfaces remain attached to the instance and they retain their IP addresses, identifiers, and attachment IDs. When the instance becomes available, all pending network traffic is flushed. Additionally, the instance remains on the same physical host, so it retains its public and private IP addresses and DNS name.
- IAM policies — IAM profiles and policies (such as tag-based policies) that are associated with the instance are retained and enforced.

- How root volume replacement works
- Considerations

- Replace a root volume

How root volume replacement works

When you replace the root volume for an instance, we create *root volume replacement task*. The original root volume is detached from the instance, and the new root volume is attached to the instance in its place. The instance's block device mapping is updated to reflect the ID of the replacement root volume.

When you replace the root volume for an instance, you must specify the source for the new volume. The following are the possible options.

Restore a root volume to its original state

This option replaces the current root volume with a volume that is based on the snapshot that was used to create it.

Considerations for using the launch state

The replacement root volume gets the same type, size, and delete on termination attributes as the original root volume.

Replace the root volume using a snapshot

This option replaces the current root volume with a replacement volume that is based on the snapshot that you specify. For example, a specific snapshot that you previously created from this root volume. This is useful if you need to recover from issues caused by corruption of the root volume or network configuration errors in the guest operating system.

The replacement root volume gets the same type, size, and delete on termination attributes as the original root volume.

Considerations for using a snapshot

- You can only use snapshots that were created directly from the instance's current or previous root volumes.
- You can't use snapshot copies created from snapshots that were taken from the root volume.
- After successfully replacing the root volume, you can still use snapshots taken from the original root volume to replace the new (replacement) root volume.

Replace the root volume using an AMI

This option replaces the current root volume using an AMI that you specify. This is useful if you need to perform operating system and application patching or upgrades. The AMI must have the same product code, billing information, architecture type, and virtualization type as the instance.

If the instance is enabled for ENA or sriov-net, then you must use an AMI that supports those features. If the instance is not enabled for ENA or sriov-net, then you can either select an AMI that doesn't include support for those features, or you can automatically add support if you select an AMI that supports ENA or sriov-net.

If the instance is enabled for NitroTPM, then you must use an AMI that has NitroTPM enabled. NitroTPM support is not enabled if the instance was not configured for it, regardless of the AMI that you select.

You can't use root volume replacement to change the boot mode of an instance. If the specified AMI has a boot mode of `uefi` or `legacy-bios`, the AMI boot mode must match the instance's `currentInstanceBootMode`. If the AMI has a boot mode of `uefi-preferred` or does not specify a boot mode, the instance continues to use its current boot mode. Before you replace the root volume, confirm that the operating system on the AMI supports the instance's current boot mode. For more information, see Determine the boot mode of an EC2 instance and Determine the boot mode of the operating system for your EC2 instance.

The replacement root volume gets the same volume type and delete on termination attribute as the original root volume. The size of the replacement root volume is the larger of the AMI root volume block device mapping size and the current root volume size.

After the root volume replacement task completes, the following new and updated information is reflected when you describe the instance using the console, AWS CLI or AWS SDKs:

- New AMI ID
- New volume ID for the root volume
- Updated NitroTPM configuration (if enabled by the AMI)
- Updated ENA configuration (if enabled by the AMI)
- Updated sriov-net configuration (if enabled by the AMI)

The new AMI ID is also reflected in the instance metadata.

Considerations for using an AMI:

- If you use an AMI that has multiple block device mappings, only the root volume of the AMI is used. The other (non-root) volumes are ignored.
- You can only use this feature if you have permissions to the AMI and its associated root volume snapshot. You cannot use this feature with AWS Marketplace AMIs.
- You can only use an AMI without a product code only if the instance does not have a product code.
- The size of the replacement root volume is the larger of the AMI root volume block device mapping size and the current root volume size.
- The instance identity documents for the instance are automatically updated.
- If the instance supports NitroTPM, the NitroTPM data for the instance is reset and new keys are generated.

Replace the root volume using an existing Amazon EBS volume

Unlike the snapshot and AMI options, which create a new volume, this option replaces the current root volume with an existing Amazon EBS volume that you have already configured. This is useful for stateful workloads, such as databases, where you want to prepare metadata or software on the root volume before you attach it to the instance.

Before you use this option, you must create and prepare the replacement Amazon EBS volume. You can prepare it by attaching it to an instance as a data volume, copying the required data to it, and then detaching it. The volume must be in the same Availability Zone as the instance.

The replacement root volume retains the size, type, and other attributes that you configured when you created and prepared it. The delete on termination attribute of the original root volume does not transfer to the replacement root volume.

Considerations for using an existing Amazon EBS volume

- The instance keeps its current boot mode. The replacement volume must contain an operating system and bootloader that support that boot mode. For more information, see Determine the boot mode of the operating system for your EC2 instance.
- The replacement volume must be in the same Availability Zone as the instance.
- The replacement volume must not be attached to any instance at the time of the request.

- The replacement volume must be in the `available` state.
- If the replacement volume does not meet these requirements, the root volume replacement request fails.
- You can use this option with AWS Marketplace instances, but both the marketplace product codes and the billing codes on the replacement volume must match those on the instance.
- If the original root volume is encrypted, the replacement volume must also be encrypted. You can move from an unencrypted volume to an encrypted one, but not from encrypted to unencrypted. When the replacement volume is encrypted, your IAM principal must have the AWS KMS permissions required to detach the original volume. You must also have the permissions to attach and decrypt the replacement volume. These are the same permissions needed to attach an encrypted volume.

You can choose whether to keep the original root volume after the root volume replacement process has completed. If you choose delete the original root volume after the replacement process completes, the original root volume is automatically deleted and becomes unrecoverable. If you choose to keep the original root volume after the process completes, the volume remains provisioned in your account; you must manually delete the volume when you no longer need it.

The root volume replacement task transitions through the following states:

- `pending` — The replacement volume is being created.
- `in-progress` — The original volume is being detached and the replacement volume is being attached.
- `succeeded` — The replacement volume has been successfully attached to the instance and the instance is available.
- `failing` — The replacement task is in the process of failing.
- `failed` — The replacement task has failed, but the root volume is still attached.
- `failing-detached` — The replacement task is in the process of failing and the instance might not have a root volume attached.
- `failed-detached` — The replacement task has failed and the instance doesn't have a root volume attached.

If the root volume replacement task fails, the instance is rebooted and the original root volume remains attached to the instance.

Considerations

Before you begin, consider the following.

Requirements

- The instance must be in the `running` state.
- The instance is automatically rebooted during the process. The contents of the memory (RAM) is erased during the reboot. No manual reboots are required.
- You can't replace the root volume if it is an instance store volume. Only instances with Amazon EBS root volumes are supported.
- You can replace the root volume for all virtualized instance types and EC2 Mac bare metal instances. No other bare metal instance types are supported.
- When using a snapshot, you can only use snapshots that you created directly from the instance's current or previous root volumes.
- If your account is enabled for Amazon EBS encryption by default in the current Region, the replacement root volume created by the root volume replacement task is always encrypted, regardless of the encryption status of the specified snapshot or the root volume of the specified AMI.

Encryption outcomes

The following table summarizes the possible encryption outcomes.

	Original root volume	Specified snapshot, AMI, or volume	Encryption by default	Replacement root volume	Encryption key used for replacement root volume
Restore replacement root volume to initial launch state	Encrypted	Not applicable	Not considered	Encrypted	Same KMS key as original root volume
	Unencrypted	Not applicable	Disabled	Unencrypted	Not applicable

	Original root volume	Specified snapshot, AMI, or volume	Encryption by default	Replacement root volume	Encryption key used for replacement root volume
	Unencrypted	Not applicable	Enabled	Encrypted	Account's default KMS key for Amazon EBS encryption
Restore replacement root volume from snapshot or AMI	Encrypted	Unencrypted	Not considered	Encrypted	Same KMS key as original root volume
	Encrypted	Encrypted	Not considered	Encrypted	Same KMS key as original root volume
	Unencrypted	Unencrypted	Disabled	Unencrypted	Not applicable
	Unencrypted	Unencrypted	Enabled	Encrypted	Account's default KMS key for Amazon EBS encryption

	Original root volume	Specified snapshot, AMI, or volume	Encryption by default	Replacement root volume	Encryption key used for replacement root volume
	Unencrypted	Encrypted	Not considered	Encrypted	If the AMI or snapshot is owned by the account, the replacement volume is encrypted with the AMI or snapshot's KMS key. If AMI or snapshot is shared with the account, replacement volume is encrypted with the account's default KMS key for Amazon EBS encryption.

	Original root volume	Specified snapshot, AMI, or volume	Encryption by default	Replacement root volume	Encryption key used for replacement root volume
Restore replacement root volume from an existing Amazon EBS volume	Encrypted	Encrypted	Not applicable	Encrypted	KMS key of the specified volume
	Encrypted	Unencrypted	Not applicable	Not allowed. You cannot replace an encrypted root volume with an unencrypted volume. Amazon EC2 rejects the replacement task.	Not applicable
	Unencrypted	Unencrypted	Not applicable	Unencrypted	Not applicable
	Unencrypted	Encrypted	Not applicable	Encrypted	KMS key of the specified volume

Replace a root volume

When you replace the root volume for an instance, a *root volume replacement task* is created. You can use the root volume replacement task to monitor the progress and outcome of the replacement process.

Console

To replace the root volume

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance for which to replace the root volume and choose **Actions**, **Monitor and troubleshoot**, **Replace root volume**.

   > **Note**
   >
   > The **Replace root volume** action is disabled if the selected instance is not in the `running` state.

4. For **Restore**, choose one of the following options:

   - **Launch state** – Restore the replacement root volume from the snapshot that was used to create the current root volume.
   - **Snapshot** – Restore the replacement root volume to the snapshot that you specify. For **Snapshot**, select the snapshot to use.
   - **Image** – Restore the replacement root volume using the AMI that you specify. For **Image**, select the AMI to use.

5. (Optional) For **Volume initialization rate**, you can specify the Amazon EBS Provisioned Rate for Volume Initialization (volume initialization rate), in MiB/s, at which the snapshot blocks are to be downloaded from Amazon S3 to the volume. For more information, see Use an Amazon EBS Provisioned Rate for Volume Initialization. To use the default initialization rate or fast snapshot restore (if it is enabled for the selected snapshot), don't specify a rate.
6. (Optional) To delete the root volume that you are replacing, select **Delete replaced root volume**.
7. Choose **Create replacement task**.
8. To monitor the replacement task, choose the **Storage** tab for the instance and expand **Recent root volume replacement tasks**.

AWS CLI

To restore the replacement root volume to the launch state

Use the create-replace-root-volume-task command. For `--instance-id`, specify the ID of the instance for which to replace the root volume. Omit the `--snapshot-id` and `--image-id` parameters. To delete the original root volume after it has been replaced, include `--delete-replaced-root-volume` and specify `true`. To specify the volume initialization rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `--volume-initialization-rate`, specify a value between `100` and `300` MiB/s.

```
aws ec2 create-replace-root-volume-task \
--instance-id i-1234567890abcdef0 \
--delete-replaced-root-volume \
--volume-initialization-rate 150
```

To restore the replacement root volume to a specific snapshot

Use the create-replace-root-volume-task command. For `--instance-id`, specify the ID of the instance for which to replace the root volume. For `--snapshot-id`, specify the ID of the snapshot to use. To delete the original root volume after it has been replaced, include `--delete-replaced-root-volume` and specify `true`. To specify the volume initialization rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `--volume-initialization-rate`, specify a value between `100` and `300` MiB/s.

```
aws ec2 create-replace-root-volume-task \
--instance-id i-1234567890abcdef0 \
--snapshot-id snap-9876543210abcdef0 \
--delete-replaced-root-volume \
--volume-initialization-rate 150
```

To restore the replacement root volume using an AMI

Use the create-replace-root-volume-task command. For `--instance-id`, specify the ID of the instance for which to replace the root volume. For `--image-id`, specify the ID of the AMI to use. To delete the original root volume after it has been replaced, include `--delete-replaced-root-volume` and specify `true`. To specify the volume initialization rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `--volume-initialization-rate`, specify a value between `100` and `300` MiB/s.

```
aws ec2 create-replace-root-volume-task \
--instance-id i-1234567890abcdef0 \
--image-id ami-09876543210abcdef \
--delete-replaced-root-volume \
--volume-initialization-rate 150
```

To replace the root volume using an existing Amazon EBS volume

Use the create-replace-root-volume-task command. For `--instance-id`, specify the ID of the instance for which to replace the root volume (for example, `i-1234567890abcdef0`). For `--volume-id`, specify the ID of the Amazon EBS volume to use as the new root volume. To delete the original root volume after the replacement completes, include `--delete-replaced-root-volume`. Amazon EC2 accepts the `--volume-initialization-rate` parameter but ignores it with this option because it does not download snapshot data.

```
aws ec2 create-replace-root-volume-task \
--instance-id i-1234567890abcdef0 \
--volume-id vol-0123456789abcdef0 \
--delete-replaced-root-volume
```

To view the status of a root volume replacement task

Use the describe-replace-root-volume-tasks command and specify the IDs of the root volume replacement tasks to view.

```
aws ec2 describe-replace-root-volume-tasks \
    --replace-root-volume-task-ids replacevol-1234567890abcdef0 \
    --query ReplaceRootVolumeTasks[].TaskState
```

The following is example output.

```
[
    "succeeded"
]
```

Alternatively, specify the `instance-id` filter to filter the results by instance.

```
$ aws ec2 describe-replace-root-volume-tasks \
```

```
    --filters Name=instance-id,Values=i-1234567890abcdef0
```

PowerShell

To restore the replacement root volume to the launch state

Use the New-EC2ReplaceRootVolumeTask command. For `-InstanceId`, specify the ID of the instance for which to replace the root volume. Omit the `-SnapshotId` and `-ImageId` parameters. To delete the original root volume after it has been replaced, include `-DeleteReplacedRootVolume` and specify `$true`. To specify the volume initialization rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `-VolumeInitializationRate`, specify a value between `100` and `300` MiB/s.

```
New-EC2ReplaceRootVolumeTask `
    -InstanceId i-1234567890abcdef0 `
    -VolumeInitializationRate 150 `
    -DeleteReplacedRootVolume $true
```

To restore the replacement root volume to a specific snapshot

Use the New-EC2ReplaceRootVolumeTask command. For `--InstanceId`, specify the ID of the instance for which to replace the root volume. For `-SnapshotId`, specify the ID of the snapshot to use. To delete the original root volume after it has been replaced, include `-DeleteReplacedRootVolume` and specify `$true`. To specify the volume initialization rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `-VolumeInitializationRate`, specify a value between `100` and `300` MiB/s.

```
New-EC2ReplaceRootVolumeTask `
    -InstanceId i-1234567890abcdef0 `
    -SnapshotId snap-9876543210abcdef0 `
    -VolumeInitializationRate 150 `
    -DeleteReplacedRootVolume $true
```

To restore the replacement root volume using an AMI

Use the New-EC2ReplaceRootVolumeTask command. For `-InstanceId`, specify the ID of the instance for which to replace the root volume. For `-ImageId`, specify the ID of the AMI to use. To delete the original root volume after it has been replaced, include `-DeleteReplacedRootVolume` and specify `$true`. To specify the volume initialization

rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `-VolumeInitializationRate`, specify a value between `100` and `300` MiB/s.

```
New-EC2ReplaceRootVolumeTask `
    -InstanceId i-1234567890abcdef0 `
    -ImageId ami-0abcdef1234567890 `
    -VolumeInitializationRate 150 `
    -DeleteReplacedRootVolume $true
```

To replace the root volume using an existing Amazon EBS volume

Use the New-EC2ReplaceRootVolumeTask command. For `-InstanceId`, specify the ID of the instance for which to replace the root volume (for example, `i-1234567890abcdef0`). For `-VolumeId`, specify the ID of the Amazon EBS volume to use as the new root volume. To delete the original root volume after the replacement completes, include `-DeleteReplacedRootVolume` and specify `$true`. Amazon EC2 accepts the `-VolumeInitializationRate` parameter but ignores it with this option because it does not download snapshot data.

```
New-EC2ReplaceRootVolumeTask `
    -InstanceId i-1234567890abcdef0 `
    -VolumeId vol-0123456789abcdef0 `
    -DeleteReplacedRootVolume $true
```

To view the status of a root volume replacement task

Use the Get-EC2ReplaceRootVolumeTask command and specify the IDs of the root volume replacement tasks to view.

```
(Get-EC2ReplaceRootVolumeTask `
    -ReplaceRootVolumeTaskIds replacevol-1234567890abcdef0).TaskState.Value
```

The following is example output.

```
Succeeded
```

Alternatively, specify the `instance-id` filter to filter the results by instance.

```
PS C:\> Get-EC2ReplaceRootVolumeTask -Filters @{Name = 'instance-id'; Values =
 'i-1234567890abcdef0'} | Format-Table
```

Device names for volumes on Amazon EC2 instances

When you attach a volume to your instance, you include a device name for the volume. This device name is used by Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume, and the name assigned can be different from the name that Amazon EC2 uses.

The number of volumes that your instance can support is determined by the operating system. For more information, see Amazon EBS volume limits for Amazon EC2 instances.

Contents

- Available device names
- Device name considerations

Available device names

Linux instances

There are two types of virtualization available for Linux instances: paravirtual (PV) and hardware virtual machine (HVM). The virtualization type of an instance is determined by the AMI used to launch the instance. All instance types support HVM AMIs. Some previous generation instance types support PV AMIs. Be sure to note the virtualization type of your AMI because the recommended and available device names that you can use depend on the virtualization type of your instance. For more information, see Virtualization types.

The following table lists the available device names that you can specify in a block device mapping or when attaching an EBS volume.

Virtualization type	Available	Reserved for root volume	Recommended for EBS data volumes	Instance store volumes
Paravirtual	/dev/sd[a-z] /dev/sd[a-z][1-15] /dev/hd[a-z]	/dev/sda1	/dev/sd[f-p] /dev/sd[f-p][1-6]	/dev/sd[b-e]

Virtualization type	Available	Reserved for root volume	Recommended for EBS data volumes	Instance store volumes
	/dev/hd[a-z][1-15]			
HVM	/dev/sd[a-z] /dev/xvd[a-c][a-z] /dev/xvdd[a-x]	Differs by AMI /dev/sda1 or /dev/xvda	/dev/sd[b-z] /dev/xvdb[b-z] *	/dev/sd[b-e] /dev/sd[b-h] (h1.16xlarge) /dev/sd[b-y] (d2.8xlarge) /dev/sd[b-i] (i2.8xlarge) **

* The device names that you specify for NVMe EBS volumes in a block device mapping are renamed using NVMe device names (`/dev/nvme[0-26]n1`). The block device driver can assign NVMe device names in a different order than you specified for the volumes in the block device mapping.

** NVMe instance store volumes are automatically enumerated and assigned an NVMe device name.

Windows instances

AWS Windows AMIs use one of the following sets of drivers to permit access to virtualized hardware:

- AWS PV: Paravirtual drivers for Windows instances
- AWS NVMe: NVMe drivers

Device names for Nitro based instances

The following table lists the available device names that you can specify in a block device mapping or when attaching an EBS volume to a Nitro based instance.

Driver type	Available	Reserved for root volume	Recommended for EBS volumes	Instance store volumes
AWS NVMe	xvd[a-z] xvd[a-c][a-z] xvdd[a-x] /dev/sda1	/dev/sda1	xvd[b-z] xvdb[b-z]	*

* NVMe instance store volumes are automatically enumerated and are assigned a Windows drive letter.

Device names for Xen based instances

The following table lists the available device names that you can specify in a block device mapping or when attaching an EBS volume to a Xen based instance.

Driver type	Available	Reserved for root volume	Recommended for EBS volumes	Instance store volumes
AWS PV	xvd[b-z] xvd[b-c][a-z] /dev/sda1 /dev/sd[b-e]	/dev/sda1	xvd[f-z]	xvdc[a-x] xvd[a-e]
Citrix PV (no longer supported)	xvd[b-z] xvd[b-c][a-z] /dev/sda1 /dev/sd[b-e]	/dev/sda1	xvd[f-z]	xvdc[a-x] xvd[a-e]

Driver type	Available	Reserved for root volume	Recommended for EBS volumes	Instance store volumes
Red Hat PV (no longer supported)	xvd[a-z] xvd[b-c][a-z] /dev/sda1 /dev/sd[b-e]	/dev/sda1	xvd[f-p]	xvdc[a-x] xvd[a-e]

For more information about instance store volumes, see Instance store temporary block storage for EC2 instances. For more information about NVMe EBS volumes (Nitro-based instances), including how to identify the EBS device, see Amazon EBS and NVMe in the *Amazon EBS User Guide*.

Device name considerations

Keep the following in mind when selecting a device name:

- The ending portion of device names that you use shouldn't overlap as it can cause issues when you start your instance. For example, avoid using combinations such as `/dev/xvdf` and `xvdf` for volumes attached to the same instance.
- Although you can attach your EBS volumes using the device names used to attach instance store volumes, we strongly recommend that you don't because the behavior can be unpredictable.
- The number of NVMe instance store volumes for an instance depends on the size of the instance. NVMe instance store volumes are automatically enumerated and assigned an NVMe device name (Linux instances) or a Windows drive letter (Windows instances).
- (Windows instances) AWS Windows AMIs come with additional software that prepares an instance when it first boots up. This is either the EC2Config service (Windows AMIs prior to Windows Server 2016) or EC2Launch (Windows Server 2016 and later). After the devices have been mapped to drives, they are initialized and mounted. The root drive is initialized and mounted as `C:\`. By default, when an EBS volume is attached to a Windows instance, it can show up as any drive letter on the instance. You can change the settings to set the drive letters of the volumes per your specifications. For instance store volumes, the default depends on the driver. AWS PV drivers and Citrix PV drivers assign instance store volumes drive letters going from Z: to A:. Red Hat drivers assign instance store volumes drive letters going from D: to Z:. For more

information, see Windows launch agents on Amazon EC2 Windows instances, and How volumes are attached and mapped for Amazon EC2 Windows instances.

- (Linux instances) Depending on the block device driver of the kernel, the device could be attached with a different name than you specified. For example, if you specify a device name of `/dev/sdh`, your device could be renamed `/dev/xvdh` or `/dev/hdh`. In most cases, the trailing letter remains the same. In some versions of Red Hat Enterprise Linux (and its variants, such as CentOS), the trailing letter could change (`/dev/sda` could become `/dev/xvde`). In these cases, the trailing letter of each device name is incremented the same number of times. For example, if `/dev/sdb` is renamed `/dev/xvdf`, then `/dev/sdc` is renamed `/dev/xvdg`. Amazon Linux creates a symbolic link for the name you specified to the renamed device. Other operating systems could behave differently.
- (Linux instances) HVM AMIs do not support the use of trailing numbers on device names, except for `/dev/sda1`, which is reserved for the root volume, and `/dev/sda2`. While using `/dev/sda2` is possible, we do not recommend using this device mapping with HVM instances.
- (Linux instances) When using PV AMIs, you cannot attach volumes that share the same device letters both with and without trailing digits. For example, if you attach a volume as `/dev/sdc` and another volume as `/dev/sdc1`, only `/dev/sdc` is visible to the instance. To use trailing digits in device names, you must use trailing digits on all device names that share the same base letters (such as `/dev/sdc1`, `/dev/sdc2`, `/dev/sdc3`).
- (Linux instances) Some custom kernels might have restrictions that limit use to `/dev/sd[f-p]` or `/dev/sd[f-p][1-6]`. If you're having trouble using `/dev/sd[q-z]` or `/dev/sd[q-z][1-6]`, try switching to `/dev/sd[f-p]` or `/dev/sd[f-p][1-6]`.

Before you specify the device name that you've selected, verify that it is available. Otherwise, you'll get an error that the device name is already in use. To view the disk devices and their mount points, use the **lsblk** command (Linux instances), or the Disk Management utility or the **diskpart** command (Windows instances).

Block device mappings for volumes on Amazon EC2 instances

Each instance that you launch has an associated root volume, which is either an Amazon EBS volume or an instance store volume. You can use block device mappings to specify additional EBS volumes or instance store volumes to attach to an instance when it's launched. You can also attach additional EBS volumes to a running instance. However, the only way to attach instance store

volumes to an instance is to use block device mappings to attach the volumes as the instance is launched.

Contents

- Block device mapping concepts
- Add block device mappings to an AMI
- Add block device mappings to Amazon EC2 instance

Block device mapping concepts

A *block device* is a storage device that moves data in sequences of bytes or bits (blocks). These devices support random access and generally use buffered I/O. Examples include hard disks, CD-ROM drives, and flash drives. A block device can be physically attached to a computer or accessed remotely as if it were physically attached to the computer.

Amazon EC2 supports two types of block devices:

- Instance store volumes (virtual devices whose underlying hardware is physically attached to the host computer for the instance)
- EBS volumes (remote storage devices)

A *block device mapping* defines the block devices (instance store volumes and EBS volumes) to attach to an instance. You can specify a block device mapping as part of creating an AMI so that the mapping is used by all instances launched from the AMI. Alternatively, you can specify a block device mapping when you launch an instance, so this mapping overrides the one specified in the AMI from which you launched the instance. Note that all NVMe instance store volumes supported by an instance type are automatically enumerated and assigned a device name on instance launch; including them in your block device mapping has no effect.

Contents

- Block device mapping entries
- Block device mapping instance store caveats
- Example block device mapping
- How devices are made available in the operating system

Block device mapping entries

When you create a block device mapping, you specify the following information for each block device that you need to attach to the instance:

- The device name used within Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume. The name assigned can be different from the name that Amazon EC2 recommends. For more information, see Device names for volumes on Amazon EC2 instances.

For Instance store volumes, you also specify the following information:

- The virtual device: `ephemeral[0-23]`. Note that the number and size of available instance store volumes for your instance varies by instance type.

For NVMe instance store volumes, the following information also applies:

- These volumes are automatically enumerated and assigned a device name; including them in your block device mapping has no effect.

For EBS volumes, you also specify the following information:

- The ID of the snapshot to use to create the block device (snap-*xxxxxxxx*). This value is optional as long as you specify a volume size. You can't specify the ID of an archived snapshot.
- The size of the volume, in GiB. The specified size must be greater than or equal to the size of the specified snapshot.
- Whether to delete the volume on instance termination (`true` or `false`). The default value is `true` for the root volume and `false` for attached volumes. When you create an AMI, its block device mapping inherits this setting from the instance. When you launch an instance, it inherits this setting from the AMI.
- The volume type, which can be gp2 and gp3 for General Purpose SSD, `io1` and `io2` for Provisioned IOPS SSD, `st1` for Throughput Optimized HDD, `sc1` for Cold HDD, or `standard` for Magnetic.
- The number of input/output operations per second (IOPS) that the volume supports. (Used only with `io1` and `io2` volumes.)

- Some instance types support more than one EBS card. You can select the EBS card for the volume to be attached to by specifying the EBS card index. For more information, see EBS cards.

Block device mapping instance store caveats

There are several caveats to consider when launching instances with AMIs that have instance store volumes in their block device mappings.

- Some instance types include more instance store volumes than others, and some instance types contain no instance store volumes at all. If your instance type supports one instance store volume, and your AMI has mappings for two instance store volumes, then the instance launches with one instance store volume.
- Instance store volumes can only be mapped at launch time. You cannot stop an instance without instance store volumes (such as the `t2.micro`), change the instance to a type that supports instance store volumes, and then restart the instance with instance store volumes. However, you can create an AMI from the instance and launch it on an instance type that supports instance store volumes, and map those instance store volumes to the instance.
- If you launch an instance with instance store volumes mapped, and then stop the instance and change it to an instance type with fewer instance store volumes and restart it, the instance store volume mappings from the initial launch still show up in the instance metadata. However, only the maximum number of supported instance store volumes for that instance type are available to the instance.

  Note

  When an instance is stopped, all data on the instance store volumes is lost.

- Depending on instance store capacity at launch time, M3 instances may ignore AMI instance store block device mappings at launch unless they are specified at launch. You should specify instance store block device mappings at launch time, even if the AMI you are launching has the instance store volumes mapped in the AMI, to ensure that the instance store volumes are available when the instance launches.

Example block device mapping

This figure shows an example block device mapping for an EBS-backed instance. It maps `/dev/sdb` to `ephemeral0` and maps two EBS volumes, one to `/dev/sdh` and the other to `/dev/sdj`. It also shows the EBS volume that is the root volume, `/dev/sda1`.

Note that this example block device mapping is used in the example commands and APIs in this topic. You can find example commands and APIs that create block device mappings in Specify a block device mapping for an AMI and Update the block device mapping when launching an instance.

How devices are made available in the operating system

Device names like `/dev/sdh` and `xvdh` are used by Amazon EC2 to describe block devices. The block device mapping is used by Amazon EC2 to specify the block devices to attach to an EC2 instance. After a block device is attached to an instance, it must be mounted by the operating system before you can access the storage device. When a block device is detached from an instance, it is unmounted by the operating system and you can no longer access the storage device.

Linux instances – The device names specified in the block device mapping are mapped to their corresponding block devices when the instance first boots. The instance type determines which instance store volumes are formatted and mounted by default. You can mount additional instance store volumes at launch, as long as you don't exceed the number of instance store volumes

available for your instance type. For more information, see Instance store temporary block storage for EC2 instances. The block device driver for the instance determines which devices are used when the volumes are formatted and mounted.

Windows instances – The device names specified in the block device mapping are mapped to their corresponding block devices when the instance first boots, and then the Ec2Config service initializes and mounts the drives. The root volume is mounted as `C:\`. The instance store volumes are mounted as `Z:\`, `Y:\`, and so on. When an EBS volume is mounted, it can be mounted using any available drive letter. However, you can configure how drive letters are assigned to EBS volumes; for more information, see the section called "Windows launch agents".

Add block device mappings to an AMI

Each AMI has a block device mapping that specifies the block devices to attach to an instance when it is launched from the AMI. To add more block devices to an AMI, you must create your own AMI.

Contents

- Specify a block device mapping for an AMI
- View the EBS volumes in an AMI block device mapping

Specify a block device mapping for an AMI

There are two ways to specify volumes in addition to the root volume when you create an AMI. If you've already attached volumes to a running instance before you create an AMI from the instance, the block device mapping for the AMI includes those same volumes. For EBS volumes, the existing data is saved to a new snapshot, and it's this new snapshot that's specified in the block device mapping. For instance store volumes, the data is not preserved.

For an EBS-backed AMI, you can add EBS volumes and instance store volumes using a block device mapping. For an Amazon S3-backed AMI, you can add instance store volumes only by modifying the block device mapping entries in the image manifest file when registering the image.

> **Note**
>
> For M3 instances, you must specify instance store volumes in the block device mapping for the instance when you launch it. When you launch an M3 instance, instance store volumes specified in the block device mapping for the AMI may be ignored if they are not specified as part of the instance block device mapping.

Console

To add volumes to an AMI

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **Instances**.
3. Select an instance and choose **Actions**, **Image and templates**, **Create image**.
4. Enter a name and a description for the image.
5. The instance volumes appear under **Instance volumes**. To add another volume, choose **Add volume**.
6. For **Volume type**, choose the volume type. For **Device** choose the device name. For an EBS volume, you can specify additional details, such as a snapshot, volume size, volume type, IOPS, and encryption state.
7. Choose **Create image**.

AWS CLI

To add volumes to an AMI

Use the create-image command to specify a block device mapping for an EBS-backed AMI. Use the register-image command to specify a block device mapping for an Amazon S3-backed AMI.

Specify the block device mapping using the `--block-device-mappings` parameter. You can specified arguments encoded in JSON directly on the command line or by referencing a JSON file, as shown here.

```
--block-device-mappings file://mapping.json
```

To add an instance store volume, use the following mapping. Note that NVMe instance store volumes are added automatically.

```
{
    "DeviceName": "device_name",
    "VirtualName": "ephemeral0"
}
```

To add an empty 100 GiB volume, use the following mapping.

```
{
    "DeviceName": "device_name",
    "Ebs": {
      "VolumeSize": 100
    }
}
```

To add an EBS volume based on a snapshot, use the following mapping.

```
{
    "DeviceName": "device_name",
    "Ebs": {
      "SnapshotId": "snap-1234567890abcdef0"
    }
}
```

To omit a mapping for a device, use the following mapping.

```
{
    "DeviceName": "device_name",
    "NoDevice": ""
}
```

PowerShell

Use the New-EC2Image cmdlet to specify a block device mapping for an EBS-backed AMI. Use the Register-EC2Image cmdlet to specify a block device mapping for an Amazon S3-backed AMI.

Add the `-BlockDeviceMapping` option, specifying the updates in `bdm`:

```
-BlockDeviceMapping $bdm
```

The following mapping adds a volume based on a snapshot.

```
$ebd = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
$ebd.SnapshotId = "snap-1234567890abcdef0"
$bdm = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$bdm.DeviceName = "device_name"
$bdm.Ebs = $ebd
```

The following mapping adds an empty 100 GB volume.

```
$ebd = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
$ebd.VolumeSize = 100
$bdm = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$bdm.DeviceName = "device_name"
$bdm.Ebs = $ebd
```

View the EBS volumes in an AMI block device mapping

You can easily enumerate the EBS volumes in the block device mapping for an AMI.

Console

To view the EBS volumes for an AMI

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **AMIs**.
3. Choose **EBS images** from the **Filter** list to get a list of EBS-backed AMIs.
4. Select the desired AMI, and look at the **Details** tab. At a minimum, the following information is available for the root volume (where the term **root device** is equivalent to **root volume**):

   - **Root Device Type** (`ebs`)
   - **Root Device Name** (for example, `/dev/sda1`)
   - **Block Devices** (for example, `/dev/sda1=snap-1234567890abcdef0:8:true`)

   If the AMI was created with additional EBS volumes using a block device mapping, the **Block Devices** field displays the mapping for those additional volumes as well. (This screen doesn't display instance store volumes.)

AWS CLI

To view the EBS volumes for an AMI

Use the describe-images command.

```
aws ec2 describe-images \
```

```
    --image-ids ami-0abcdef1234567890 \
    --query Image[0].BlockDeviceMappings
```

PowerShell

To view the EBS volumes for an AMI

Use the Get-EC2Image cmdlet.

```
(Get-EC2Image -ImageId ami-0abcdef1234567890).BlockDeviceMappings
```

Add block device mappings to Amazon EC2 instance

By default, an instance that you launch includes any storage devices specified in the block device mapping of the AMI from which you launched the instance. You can specify changes to the block device mapping for an instance when you launch it, and these updates overwrite or merge with the block device mapping of the AMI.

Limitations

- For the root volume, you can only modify the following: volume size, volume type, and the **Delete on Termination** flag.
- When you modify an EBS volume, you can't decrease its size. Therefore, you must specify a snapshot whose size is equal to or greater than the size of the snapshot specified in the block device mapping of the AMI.

Tasks

- Update the block device mapping when launching an instance
- Update the block device mapping of a running instance
- View the EBS volumes in an instance block device mapping
- View the instance block device mapping for instance store volumes

Update the block device mapping when launching an instance

You can add EBS volumes and instance store volumes to an instance when you launch it. Note that updating the block device mapping for an instance doesn't make a permanent change to the block device mapping of the AMI from which it was launched.

Console

To update the volumes for an instance at launch

1. Follow the procedure to launch an instance, but don't launch the instance until you've completed the following steps to update the volumes.
2. (Optional) To add a volume, choose **Configure storage**, **Add new volume**. Select the volume size and volume type.
3. (Optional) To suppress a volume that was specified by the block device mapping of the AMI, choose **Configure storage**, **Remove**.
4. (Optional) To modify the configuration of an EBS volume, on the **Configure storage** pane, choose **Advanced**. Expand the information for the volume, and make whatever changes you need.
5. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see Launch an EC2 instance using the launch instance wizard in the console.

AWS CLI

To update the volumes for an instance at launch

Use the run-instances command with the `--block-device-mappings` option.

```
--block-device-mappings file://mapping.json
```

For example, suppose that an AMI block device mapping specifies the following:

- `/dev/xvda` - EBS root volume
- `/dev/sdh` - EBS volume created from `snap-1234567890abcdef0`
- `/dev/sdj` - Empty EBS volume with a size of `100`
- `/dev/sdb` - Instance store volume `ephemeral0`

Suppose that the following is the instance block device mapping in `mapping.json`.

```
[
    {
```

```
        "DeviceName": "/dev/xvda",
        "Ebs": {
            "VolumeSize": 100
        }
    },
    {
        "DeviceName": "/dev/sdj",
        "NoDevice": ""
    },
    {
        "DeviceName": "/dev/sdh",
        "Ebs": {
            "VolumeSize": 300
        }
    },
    {
        "DeviceName": "/dev/sdc",
        "VirtualName": "ephemeral1"
    }
]
```

The instance block device mapping does the following:

- Overrides the size of the root volume, `/dev/xvda`, increasing it to 100 GiB.
- Prevents `/dev/sdj` from attaching to the instance.
- Overrides the size of `/dev/sdh`, increasing it to 300 GiB. Notice that you don't need to specify the snapshot ID again.
- Adds an ephemeral volume, `/dev/sdc`. If the instance type doesn't support multiple instance store volumes, this has no effect. If the instance type supports NVMe instance store volumes, they are automatically enumerated and included in the instance block device mapping and can't be overridden.

PowerShell

To update the volumes for an instance at launch

Use the `-BlockDeviceMapping` parameter with the New-EC2Instance cmdlet with the `-BlockDeviceMapping` parameter.

```
-BlockDeviceMapping $bdm
```

Suppose that the following is the instance block device mapping in `$bdm`.

```
$bdm = @()

$root = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$root.DeviceName = "/dev/xvda"
$ebs1 = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
$ebs1.VolumeSize = 100
$root.Ebs = $ebs1
$bdm += $root

$sdj = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdj.DeviceName = "/dev/sdj"
$sdj.NoDevice = ""
$bdm += $sdj

$sdh = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdh.DeviceName = "/dev/sdh"
$ebs2 = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
$ebs2.VolumeSize = 300
$sdh.Ebs = $ebs2
$bdm += $sdh

$sdc = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdc.DeviceName = "/dev/sdc"
$sdc.VirtualName = "ephemeral1"
$bdm += $sdc
```

The instance block device mapping does the following:

- Overrides the size of the root volume, `/dev/xvda`, increasing it to 100 GiB.
- Prevents `/dev/sdj` from attaching to the instance.
- Overrides the size of `/dev/sdh`, increasing it to 300 GiB. Notice that you don't need to specify the snapshot ID again.
- Adds an ephemeral volume, `/dev/sdc`. If the instance type doesn't support multiple instance store volumes, this has no effect. If the instance type supports NVMe instance store volumes, they are automatically enumerated and included in the instance block device mapping and can't be overridden.

Update the block device mapping of a running instance

You do not need to stop the instance before changing this attribute.

AWS CLI

To update the block device mapping of a running instance

Use the modify-instance-attribute command.

Add the `--block-device-mappings` option:

```
--block-device-mappings file://mapping.json
```

In `mapping.json`, specify the updates. For example, the following update changes the root volume to persist.

```
[
  {
    "DeviceName": "/dev/sda1",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

PowerShell

To update the block device mapping of a running instance

Use the Edit-EC2InstanceAttribute cmdlet.

Add the `-BlockDeviceMapping` option:

```
-BlockDeviceMapping $bdm
```

In `bdm`, specify the updates. For example, the following update changes the root volume to persist.

```
$ebd = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
```

```
$ebd.DeleteOnTermination = false
$bdm = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$bdm.DeviceName = "/dev/sda1"
$bdm.Ebs = $ebd
```

View the EBS volumes in an instance block device mapping

You can easily enumerate the EBS volumes mapped to an instance.

Console

To view the EBS volumes for an instance

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **Instances**.
3. Select the instance and look at the details displayed in the **Storage** tab. At a minimum, the following information is available for the root volume (where the term **root device** is equivalent to **root volume**):

   - **Root device type** (for example, **EBS**)
   - **Root device name** (for example, `/dev/xvda`)
   - **Block devices** (for example, `/dev/xvda`, `/dev/sdf`, and `/dev/sdj`)

   If the instance was launched with additional EBS volumes using a block device mapping, they appear under **Block devices**. Any instance store volumes do not appear on this tab.
4. To display additional information about an EBS volume, choose its volume ID to go to the volume page.

AWS CLI

To view the EBS volumes for an instance

Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query Reservations[*].Instances[0].BlockDeviceMappings
```

PowerShell

To view the EBS volumes for an instance

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance -InstanceId i-0bac57d7472c89bac).Instances.BlockDeviceMappings
```

View the instance block device mapping for instance store volumes

The instance type determines the number and type of instance store volumes that are available to the instance. If the number of instance store volumes in a block device mapping exceeds the number of instance store volumes available to an instance, the additional volumes are ignored. To view the instance store volumes for your instance, run the **lsblk** command (Linux instances) or open **Windows Disk Management** (Windows instances). To learn how many instance store volumes are supported by each instance type, see Amazon EC2 instance type specifications.

When you view the block device mapping for your instance, you can see only the EBS volumes, not the instance store volumes. The method you use to view the instance store volumes for your instance depends on the volume type.

NVMe instance store volumes

Linux instances

You can use the NVMe command line package, nvme-cli, to query the NVMe instance store volumes in the block device mapping. Download and install the package on your instance, and then run the following command.

```
[ec2-user ~]$ sudo nvme list
```

The following is example output for an instance. The text in the Model column indicates whether the volume is an EBS volume or an instance store volume. In this example, both `/dev/nvme1n1` and `/dev/nvme2n1` are instance store volumes.

```
Node             SN                   Model
 Namespace
```

```
---------------- -------------------- ----------------------------------------
 ---------
/dev/nvme0n1     vol06afc3f8715b7a597 Amazon Elastic Block Store              1

/dev/nvme1n1     AWS2C1436F5159EB6614 Amazon EC2 NVMe Instance Storage        1

/dev/nvme2n1     AWSB1F4FF0C0A6C281EA Amazon EC2 NVMe Instance Storage        1
  ...
```

Windows instances

You can use Disk Management or PowerShell to list both EBS and instance store NVMe volumes. For more information, see the section called “Map NVME disks to volumes”.

HDD or SSD instance store volumes

You can use instance metadata to query the HDD or SSD instance store volumes in the block device mapping. NVMe instance store volumes are not included.

The base URI for all requests for instance metadata is `http://169.254.169.254/latest/`. For more information, see Use instance metadata to manage your EC2 instance.

Linux instances

First, connect to your running instance. From the instance, use this query to get its block device mapping.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-
aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-
data/block-device-mapping/
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/block-device-mapping/
```

The response includes the names of the block devices for the instance. For example, the output for an instance store–backed `m1.small` instance looks like this.

```
ami
ephemeral0
root
swap
```

The `ami` device is the root volume as seen by the instance. The instance store volumes are named `ephemeral[0-23]`. The `swap` device is for the page file. If you've also mapped EBS volumes, they appear as `ebs1`, `ebs2`, and so on.

To get details about an individual block device in the block device mapping, append its name to the previous query, as shown here.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/block-device-mapping/ephemeral0
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/block-device-mapping/ephemeral0
```

Windows instances

First, connect to your running instance. From the instance, use this query to get its block device mapping.

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/block-device-mapping/
```

The response includes the names of the block devices for the instance. For example, the output for an instance store–backed `m1.small` instance looks like this.

```
ami
ephemeral0
root
```

```
swap
```

The `ami` device is the root volume as seen by the instance. The instance store volumes are named `ephemeral[0-23]`. The `swap` device is for the page file. If you've also mapped EBS volumes, they appear as `ebs1`, `ebs2`, and so on.

To get details about an individual block device in the block device mapping, append its name to the previous query, as shown here.

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/block-device-mapping/ephemeral0
```

How volumes are attached and mapped for Amazon EC2 Windows instances

> **Note**
>
> This topic applies to Windows instances only.

Your Windows instance comes with an EBS volume that serves as the root volume. If your Windows instance uses AWS PV or Citrix PV drivers, you can optionally add up to 25 volumes, making a total of 26 volumes. For more information, see Amazon EBS volume limits for Amazon EC2 instances.

Depending on the instance type of your instance, you'll have from 0 to 24 possible instance store volumes available to the instance. To use any of the instance store volumes that are available to your instance, you must specify them when you create your AMI or launch your instance. You can also add EBS volumes when you create your AMI or launch your instance, or attach them while your instance is running.

When you add a volume to your instance, you specify the device name that Amazon EC2 uses. For more information, see Device names for volumes on Amazon EC2 instances. AWS Windows Amazon Machine Images (AMIs) contain a set of drivers that are used by Amazon EC2 to map instance store and EBS volumes to Windows disks and drive letters.

Methods to map disks to EBS volumes

- Map NVMe disks on Amazon EC2 Windows instance to volumes

- Map non-NVMe disks on Amazon EC2 Windows instance to volumes

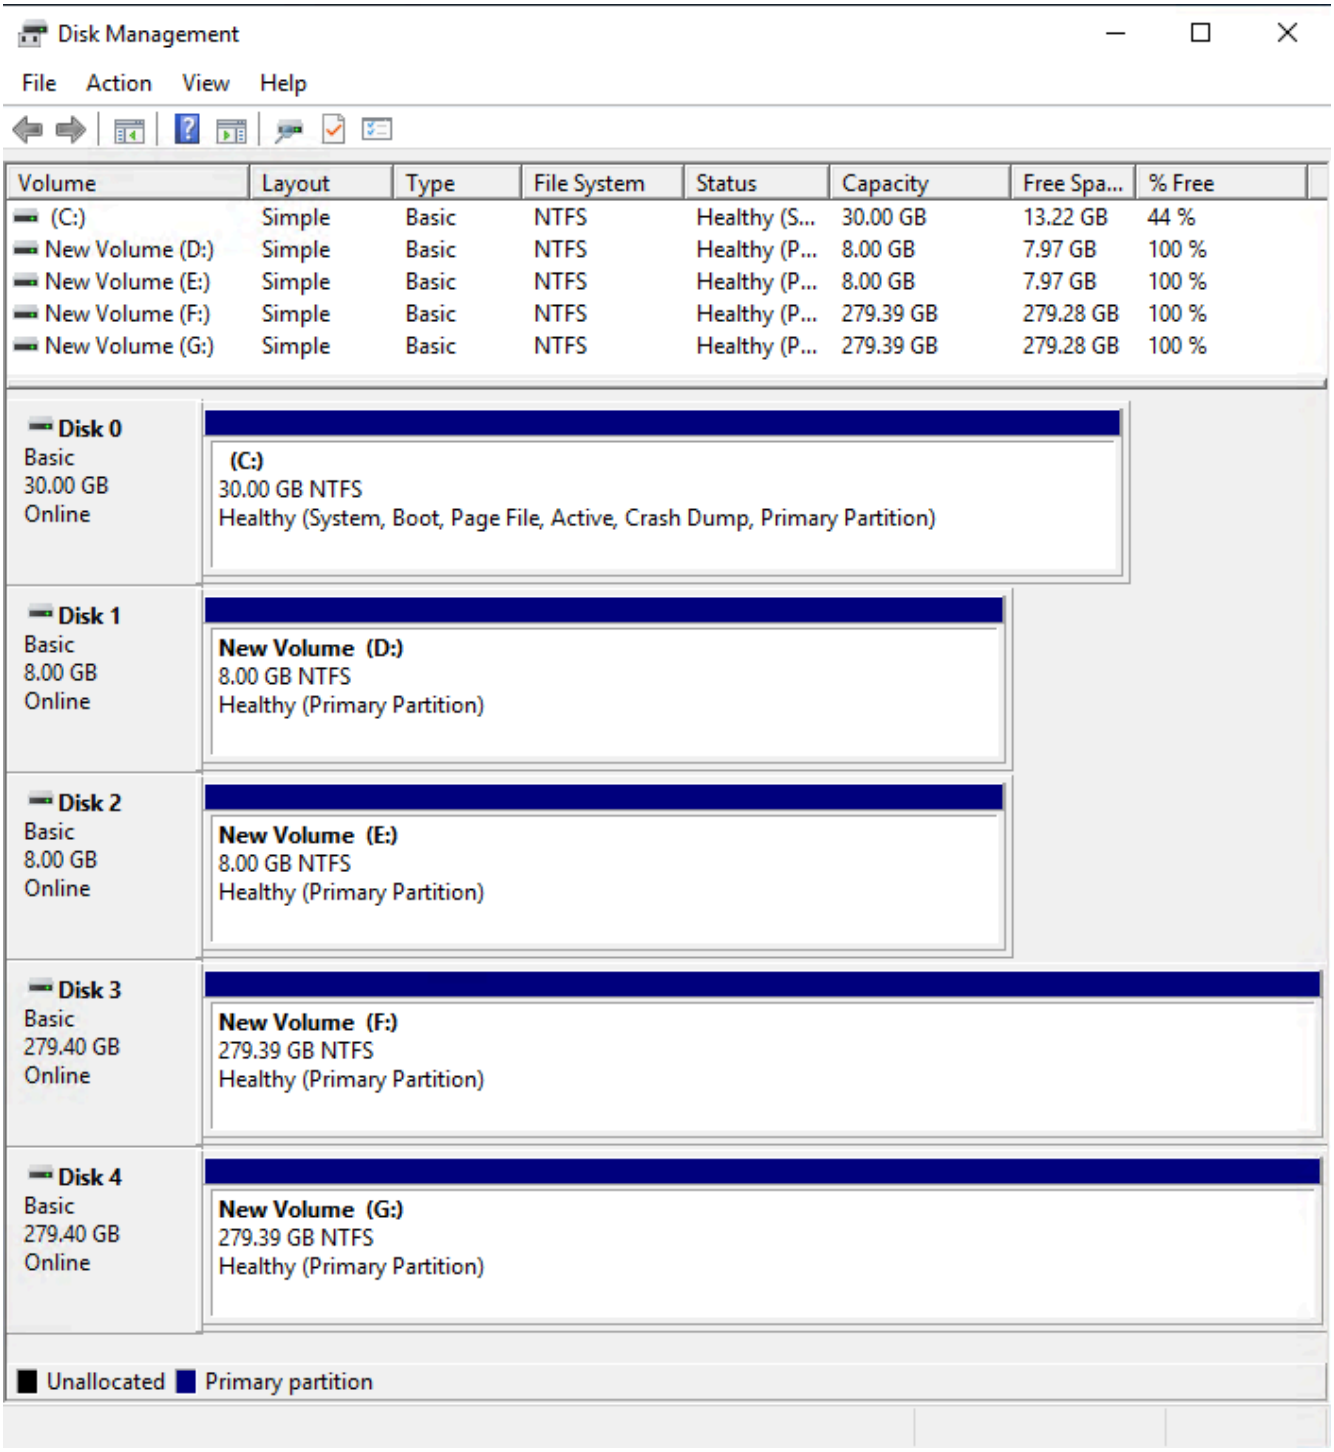
Map NVMe disks on Amazon EC2 Windows instance to volumes

With Nitro-based instances, EBS volumes are exposed as NVMe devices. This topic explains how to view the **NVMe disks** that are available to the Windows operating system on your instance. It also shows how to map those NVMe disks to the underlying Amazon EBS volumes and the device names specified for the block device mappings used by Amazon EC2.

Topics

- List NVMe disks
- Map NVMe disks to volumes

List NVMe disks



You can find the disks on your Windows instance using Disk Management or Powershell.

Disk Management

To find the disks on your Windows instance

1. Log in to your Windows instance using Remote Desktop. For more information, see Connect to your Windows instance using RDP.
2. Start the Disk Management utility.
3. Review the disks. The root volume is an EBS volume mounted as `C:\`. If there are no other disks shown, then you didn't specify additional volumes when you created the AMI or launched the instance.

   The following is an example that shows the disks that are available if you launch an `r5d.4xlarge` instance with two additional EBS volumes.

PowerShell

The following PowerShell script lists each disk and its corresponding device name and volume. It is intended for use with Nitro-based instances, which use NVMe EBS and instance store volumes.

Connect to your Windows instance and run the following command to enable PowerShell script execution.

```
Set-ExecutionPolicy RemoteSigned
```

Copy the following script and save it as `mapping.ps1` on your Windows instance.

```
# List the disks for NVMe volumes

function Get-EC2InstanceMetadata {
    param([string]$Path)
    (Invoke-WebRequest -Uri "http://169.254.169.254/latest/$Path").Content
}

function GetEBSVolumeId {
    param($Path)
    $SerialNumber = (Get-Disk -Path $Path).SerialNumber
    if($SerialNumber -clike 'vol*'){
        $EbsVolumeId = $SerialNumber.Substring(0,20).Replace("vol","vol-")
    }
    else {
       $EbsVolumeId = $SerialNumber.Substring(0,20).Replace("AWS","AWS-")
    }
    return $EbsVolumeId
}

function GetDeviceName{
    param($EbsVolumeId)
    if($EbsVolumeId -clike 'vol*'){

        $Device  = ((Get-EC2Volume -VolumeId $EbsVolumeId ).Attachment).Device
        $VolumeName = ""
    }
     else {
        $Device = "Ephemeral"
        $VolumeName = "Temporary Storage"
    }
    Return $Device,$VolumeName
}

function GetDriveLetter{
    param($Path)
    $DiskNumber =  (Get-Disk -Path $Path).Number
```

```
    if($DiskNumber -eq 0){
        $VirtualDevice = "root"
        $DriveLetter = "C"
        $PartitionNumber = (Get-Partition -DriveLetter C).PartitionNumber
    }
    else
    {
        $VirtualDevice = "N/A"
        $DriveLetter = (Get-Partition -DiskNumber $DiskNumber).DriveLetter
        if(!$DriveLetter)
        {
            $DriveLetter = ((Get-Partition -DiskId $Path).AccessPaths).Split(",")[0]
        }
        $PartitionNumber = (Get-Partition -DiskId $Path).PartitionNumber
    }

    return $DriveLetter,$VirtualDevice,$PartitionNumber

}

$Report = @()
foreach($Path in (Get-Disk).Path)
{
    $Disk_ID = ( Get-Partition -DiskId $Path).DiskId
    $Disk = ( Get-Disk -Path $Path).Number
    $EbsVolumeId  = GetEBSVolumeId($Path)
    $Size =(Get-Disk -Path $Path).Size
    $DriveLetter,$VirtualDevice, $Partition = (GetDriveLetter($Path))
    $Device,$VolumeName = GetDeviceName($EbsVolumeId)
    $Disk = New-Object PSObject -Property @{
      Disk          = $Disk
      Partitions    = $Partition
      DriveLetter   = $DriveLetter
      EbsVolumeId   = $EbsVolumeId
      Device        = $Device
      VirtualDevice = $VirtualDevice
      VolumeName= $VolumeName
    }
 $Report += $Disk
}

$Report | Sort-Object Disk | Format-Table -AutoSize -Property Disk, Partitions,
 DriveLetter, EbsVolumeId, Device, VirtualDevice, VolumeName
```

Run the script as follows:

```
PS C:\> .\mapping.ps1
```

The following is example output for an instance with a root volume, two EBS volumes, and two instance store volumes.

```
Disk Partitions DriveLetter EbsVolumeId           Device    VirtualDevice VolumeName
---- ---------- ----------- -----------           ------    ------------- ----------
   0          1 C           vol-03683f1d861744bc7 /dev/sda1 root
   1          1 D           vol-082b07051043174b9 xvdb      N/A
   2          1 E           vol-0a4064b39e5f534a2 xvdc      N/A
   3          1 F           AWS-6AAD8C2AEEE1193F0 Ephemeral N/A           Temporary
 Storage
   4          1 G           AWS-13E7299C2BD031A28 Ephemeral N/A           Temporary
 Storage
```

If you did not configure your credentials for Tools for Windows PowerShell on the Windows instance, the script cannot get the EBS volume ID and uses N/A in the `EbsVolumeId` column.

Map NVMe disks to volumes

You can use the Get-Disk command to map Windows disk numbers to Amazon EBS volumes and Amazon EC2 instance store volumes.

```
PS C:\> Get-Disk
Number Friendly Name Serial Number                    HealthStatus
 OperationalStatus      Total Size Partition

                      Style
------ ------------- -------------                    ------------
 -----------------      ---------- ----------
3      NVMe Amazo... AWS6AAD8C2AEEE1193F0_00000001.   Healthy              Online
              279.4 GB MBR
4      NVMe Amazo... AWS13E7299C2BD031A28_00000001.   Healthy              Online
              279.4 GB MBR
2      NVMe Amazo... vol0a4064b39e5f534a2_00000001.   Healthy              Online
                  8 GB MBR
0      NVMe Amazo... vol03683f1d861744bc7_00000001.   Healthy              Online
                 30 GB MBR
```

```
1      NVMe Amazo... vol082b07051043174b9_00000001.   Healthy              Online
                  8 GB MBR
```

You can also run the **ebsnvme-id** command to map NVMe disk numbers to EBS volume IDs and device names.

```
PS C:\> C:\PROGRAMDATA\Amazon\Tools\ebsnvme-id.exe
Disk Number: 0
Volume ID: vol-03683f1d861744bc7
Device Name: sda1

Disk Number: 1
Volume ID: vol-082b07051043174b9
Device Name: xvdb

Disk Number: 2
Volume ID: vol-0a4064b39e5f534a2
Device Name: xvdc
```

Map non-NVMe disks on Amazon EC2 Windows instance to volumes

For instances launched from a Windows AMI that uses AWS PV or Citrix PV drivers, you can use the relationships described on this page to map your Windows disks to your instance store and EBS volumes. This topic explains how to view the **non-NVMe disks** that are available to the Windows operating system on your instance. It also shows how to map those non-NVMe disks to the underlying Amazon EBS volumes and the device names specified for the block device mappings used by Amazon EC2.

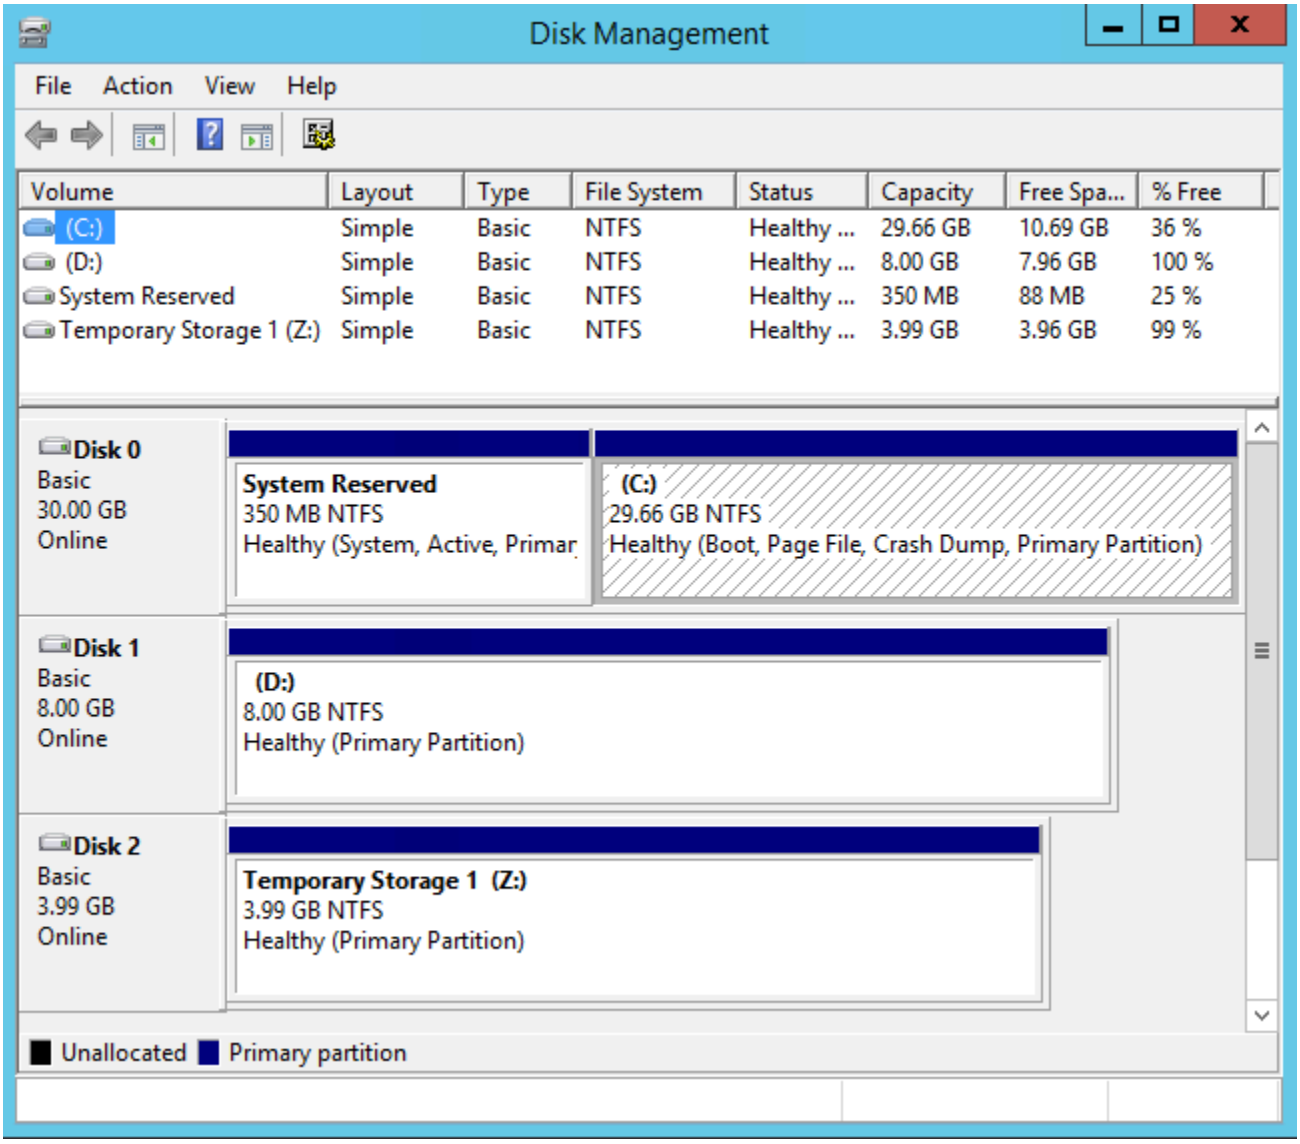
> **Note**
>
> If you launch an instance If your Windows AMI uses Red Hat PV drivers, you can update your instance to use the Citrix drivers. For more information, see the section called "Upgrade PV drivers".

Topics

- List non-NVMe disks
- Map non-NVMe disks to volumes

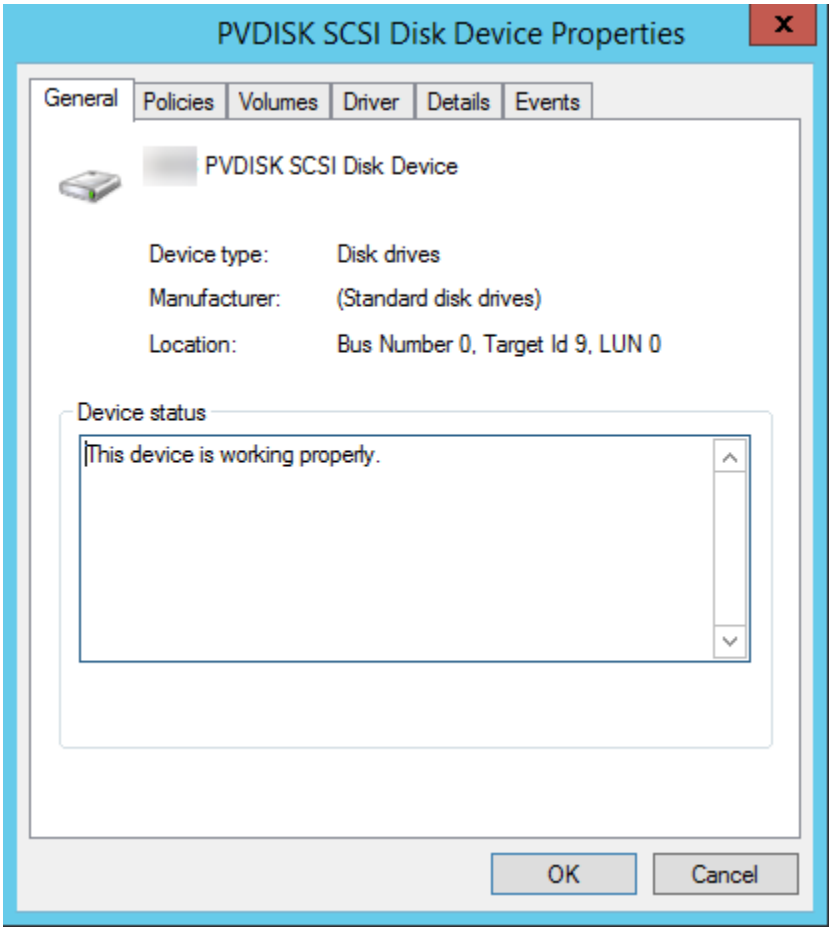
List non-NVMe disks

You can find the disks on your Windows instance using Disk Management or PowerShell.



Disk Management

To find the disks on your Windows instance



1. Log in to your Windows instance using Remote Desktop. For more information, see Connect to your Windows instance using RDP.
2. Start the Disk Management utility.

   On the taskbar, open the context (right-click) menu for the Windows logo, and then choose **Disk Management**.
3. Review the disks. The root volume is an EBS volume mounted as `C:\`. If there are no other disks shown, then you didn't specify additional volumes when you created the AMI or launched the instance.

   The following is an example that shows the disks that are available if you launch an `m3.medium` instance with an instance store volume (Disk 2) and an additional EBS volume (Disk 1).

4. Open the context (right-click) menu for the gray pane labeled Disk 1, and then select **Properties**. Note the value of **Location** and look it up in the tables in Map non-NVMe disks to volumes. For example, the following disk has the location Bus Number 0, Target Id 9, LUN 0. According to the table for EBS volumes, the device name for this location is `xvdj`.

PowerShell

The following PowerShell script lists each disk and its corresponding device name and volume.

Requirements and limitations

- Requires Windows Server 2012 or later.
- Requires credentials to get the EBS volume ID. You can configure a profile using the Tools for PowerShell, or attach an IAM role to the instance.
- Does not support NVMe volumes.
- Does not support dynamic disks.

Connect to your Windows instance and run the following command to enable PowerShell script execution.

```
Set-ExecutionPolicy RemoteSigned
```

Copy the following script and save it as `mapping.ps1` on your Windows instance.

```
# List the disks
function Convert-SCSITargetIdToDeviceName {
  param([int]$SCSITargetId)
  If ($SCSITargetId -eq 0) {
    return "sda1"
  }
  $deviceName = "xvd"
  If ($SCSITargetId -gt 25) {
    $deviceName += [char](0x60 + [int]($SCSITargetId / 26))
  }
  $deviceName += [char](0x61 + $SCSITargetId % 26)
  return $deviceName
}

[string[]]$array1 = @()
[string[]]$array2 = @()
[string[]]$array3 = @()
[string[]]$array4 = @()

          $DriveLetter = $array[0][$i]
          $DeviceName = $array[3][$i]
        }
        $i ++
      }
    }
    $BlockDevice = ""
    $BlockDeviceName = ($BlockDeviceMappings | Where-Object { $_.ebs.VolumeId -eq
 $EbsVolumeID }).DeviceName
  }
  ElseIf ($DiskDrive.path -like "*NETAPP*") {
    if ($DriveLetter -match '[^a-zA-Z0-9]') {
      $i = 0
      While ($i -ne ($array3.Count)) {
        if ($array[2][$i] -eq $EbsVolumeID) {
          $DriveLetter = $array[0][$i]
          $DeviceName = $array[3][$i]
        }
        $i ++
      }
    }
    $EbsVolumeID = "FSxN Volume"
    $BlockDevice = ""
    $BlockDeviceName = ($BlockDeviceMappings | Where-Object { $_.ebs.VolumeId -eq
 $EbsVolumeID }).DeviceName
  }
  Else {
    $BlockDeviceName = $null
    $BlockDevice = $null
  }
```

```
  New-Object PSObject -Property @{
    Disk          = $Disk;
    Partitions    = $Partitions;
    DriveLetter   = If ($DriveLetter -eq $null) { "N/A" } Else { $DriveLetter };
    EbsVolumeId   = If ($EbsVolumeID -eq $null) { "N/A" } Else { $EbsVolumeID };
    Device        = If ($BlockDeviceName -eq $null) { "N/A" } Else
 { $BlockDeviceName };
    VirtualDevice = If ($VirtualDevice -eq $null) { "N/A" } Else { $VirtualDevice };
    VolumeName    = If ($VolumeName -eq $null) { "N/A" } Else { $VolumeName };
    DeviceName    = If ($DeviceName -eq $null) { "N/A" } Else { $DeviceName };
  }
} | Sort-Object Disk | Format-Table -AutoSize -Property Disk, Partitions,
 DriveLetter, EbsVolumeId, Device, VirtualDevice, DeviceName, VolumeName
```

Run the script as follows:

```
PS C:\> .\mapping.ps1
```

The following is example output.

```
Disk  Partitions  DriveLetter   EbsVolumeId             Device      VirtualDevice
 DeviceName              VolumeName
----  ----------  -----------   -----------             ------      -------------
 ----------              ----------
   0           1            C   vol-0561f1783298efedd   /dev/sda1   N/A
 NVMe Amazon Elastic B   N/A
   1           1            D   vol-002a9488504c5e35a   xvdb        N/A
 NVMe Amazon Elastic B   N/A
   2           1            E   vol-0de9d46fcc907925d   xvdc        N/A
 NVMe Amazon Elastic B   N/A
```

If you did not provide your credentials on the Windows instance, the script cannot get the EBS volume ID and uses N/A in the `EbsVolumeId` column.

Map non-NVMe disks to volumes

The block device driver for the instance assigns the actual volume names when mounting volumes.

Mappings

- Instance store volumes

- EBS volumes

Instance store volumes

The following table describes how the Citrix PV and AWS PV drivers map non-NVMe instance store volumes to Windows volumes. The number of available instance store volumes is determined by the instance type. For more information, see Instance store volume limits for EC2 instances.

Location	Device name
Bus Number 0, Target ID 78, LUN 0	xvdca
Bus Number 0, Target ID 79, LUN 0	xvdcb
Bus Number 0, Target ID 80, LUN 0	xvdcc
Bus Number 0, Target ID 81, LUN 0	xvdcd
Bus Number 0, Target ID 82, LUN 0	xvdce
Bus Number 0, Target ID 83, LUN 0	xvdcf
Bus Number 0, Target ID 84, LUN 0	xvdcg
Bus Number 0, Target ID 85, LUN 0	xvdch
Bus Number 0, Target ID 86, LUN 0	xvdci
Bus Number 0, Target ID 87, LUN 0	xvdcj
Bus Number 0, Target ID 88, LUN 0	xvdck
Bus Number 0, Target ID 89, LUN 0	xvdcl

EBS volumes

The following table describes how the Citrix PV and AWS PV drivers map non-NVME EBS volumes to Windows volumes.

Location	Device name
Bus Number 0, Target ID 0, LUN 0	/dev/sda1
Bus Number 0, Target ID 1, LUN 0	xvdb
Bus Number 0, Target ID 2, LUN 0	xvdc
Bus Number 0, Target ID 3, LUN 0	xvdd
Bus Number 0, Target ID 4, LUN 0	xvde
Bus Number 0, Target ID 5, LUN 0	xvdf
Bus Number 0, Target ID 6, LUN 0	xvdg
Bus Number 0, Target ID 7, LUN 0	xvdh
Bus Number 0, Target ID 8, LUN 0	xvdi
Bus Number 0, Target ID 9, LUN 0	xvdj
Bus Number 0, Target ID 10, LUN 0	xvdk
Bus Number 0, Target ID 11, LUN 0	xvdl
Bus Number 0, Target ID 12, LUN 0	xvdm
Bus Number 0, Target ID 13, LUN 0	xvdn
Bus Number 0, Target ID 14, LUN 0	xvdo
Bus Number 0, Target ID 15, LUN 0	xvdp
Bus Number 0, Target ID 16, LUN 0	xvdq
Bus Number 0, Target ID 17, LUN 0	xvdr
Bus Number 0, Target ID 18, LUN 0	xvds
Bus Number 0, Target ID 19, LUN 0	xvdt

Location	Device name
Bus Number 0, Target ID 20, LUN 0	xvdu
Bus Number 0, Target ID 21, LUN 0	xvdv
Bus Number 0, Target ID 22, LUN 0	xvdw
Bus Number 0, Target ID 23, LUN 0	xvdx
Bus Number 0, Target ID 24, LUN 0	xvdy
Bus Number 0, Target ID 25, LUN 0	xvdz

Torn write prevention on Amazon EC2 Linux instances

Note

Torn write prevention is supported for Linux instances only.

Torn write prevention is a block storage feature designed by AWS to improve the performance of your I/O-intensive relational database workloads and reduce latency without negatively impacting data resiliency. Relational databases that use InnoDB or XtraDB as the database engine, such as MySQL and MariaDB, will benefit from torn write prevention.

Typically, relational databases that use pages larger than the *power fail atomicity* of the storage device use *data logging* mechanisms to protect against torn writes. MariaDB and MySQL use a *doublewrite buffer* file to log data before writing it to data tables. In the event of incomplete or torn writes, as a result of operating system crashes or power loss during write transactions, the database can recover the data from the doublewrite buffer. The additional I/O overhead associated with writing to the doublewrite buffer impacts database performance and application latency, and it reduces the number transactions that can be processed per second. For more information about doublewrite buffer, see the MariaDB and MySQL documentation.

With *torn write prevention*, data is written to storage in *all-or-nothing* write transactions, which eliminates the need for using the doublewrite buffer. This prevents partial, or torn, data from being written to storage in the event of operating system crashes or power loss during write transactions.

The number of transactions processed per second can be increased by up to 30 percent, and write latency can be decreased by up to 50 percent, without compromising the resiliency of your workloads.

Pricing

There are no additional costs for using torn write prevention.

Block sizes for torn write prevention on Amazon EC2

Torn write prevention supports write operations for 4 KiB, 8 KiB, and 16 KiB blocks of data. The data block start logical block address (LBA) must be aligned to the respective block boundary size of 4 KiB, 8 KiB, or 16 KiB. For example, for 16 KiB write operations, the data block start LBA must be aligned to a block boundary size of 16 KiB.

The following table shows support across storage and instance types.

	4 KiB blocks	8 KiB blocks	16 KiB blocks
Instance store volumes	All NVMe instance store volumes attached to current generation I-family instances.	I4i, Im4gn, Is4gen, I7i, I7ie, I8g, and I8ge instances supported by AWS Nitro SSD.	
Amazon EBS volumes	All Amazon EBS volumes attached to Nitro-based instances.		

To confirm whether your instance and volume support torn write prevention, query to check if the instance supports torn write prevention and other details, like supported block and boundary sizes. For more information, see Check Amazon EC2 instance support for torn write prevention.

Requirements for using torn write prevention on Amazon EC2

For torn write prevention to work properly, an I/O operation must meet size, alignment, and boundary requirements, as specified in the NTWPU, NTWGU, NTWBU fields. You must configure your operating system to ensure that the specific storage subsystem (file system, LVM, RAID, etc) does not modify I/O properties down the storage stack, including block merges, splits, or block address relocation, before being submitted to the device.

Torn write prevent has been tested with the following configuration:

- An instance type and storage type that supports the required block size.
- Amazon Linux 2 with kernel version 5.10 or later.
- ext4 with `bigalloc` enabled and a cluster size of 16 KiB, and the most recent ext4 utilities (e2fsprogs 1.46.5 or later).
- `O_DIRECT` file access mode to bypass Linux kernel buffer cache.

> **Note**
>
> You do not need to disable I/O merging for MySQL and MariaDB workloads.

Check Amazon EC2 instance support for torn write prevention

To confirm whether your instance and volume supports torn write prevention, and to view the NVMe namespace vendor-specific data that contains torn write prevention information, use the following command.

```
$ sudo nvme id-ns -v device_name
```

> **Note**
>
> The command returns the vendor-specific information in hex with ASCII interpretation. You might need to build a tool, similar to `ebsnvme-id`, into your applications that can read and parse the output.

For example, the following command returns the NVMe namespace vendor-specific data that contains torn write prevention information for /dev/nvme1n1.

```
$ sudo nvme id-ns -v /dev/nvme1n1
```

If your instance and volume support torn write prevention, it returns the following AWS torn write prevention information in the NVMe namespace vendor-specific data.

Note

The bytes in the following table represent the offset in bytes from the beginning of the NVMe namespace vendor-specific data.

Bytes	Description
0:31	The name of the device attachment mount point, for example /dev/xvda . You provide this during volume attachment request and it can be used by the Amazon EC2 instance to create a symlink to the NVMe block device(nvmeXn1).
32:63	The volume ID. For example, vol01234567890abcdef . This field can be used to map the NVMe device to the attached volume.
64:255	Reserved for future use.
256:257	Namespace Torn Write Prevention Unit size (NTWPU). This field indicates the namespace specific size of the write operation guaranteed to be written atomically to the NVM during a power failure or error condition. This field is specified in logical blocks represented in zero based values.
258:259	Namespace Torn Write Prevention Granularity size (NTWPG). This field indicates the namespace specific size increments below NTWPU of the write operation guaranteed to be written atomically to the NVM during a power failure or error condition. That is, size should be NTWPG * n <= NTWPU where n is positive integer. The write operation LBA offset

Bytes	Description
	also must be aligned to this field. This field is specified in logical blocks represented in zero based values.
260:263	Namespace Torn Write Prevention Boundary size (NTWPB). This field indicates the atomic boundary size for this namespace for the NTWPU value. Writes to this namespace that cross atomic boundaries are not guaranteed to be written atomically to the NVM during a power failure or error condition. A value of 0h indicates that there are no atomic boundaries for power fail or error conditions. All other values specify a size in terms of logical blocks using the same encoding as the NTWPU field.

Configure your workload on Amazon EC2 for torn write prevention

Torn write prevention is enabled by default on supported instance types with supported volumes. You don't need to configure any additional settings to enable torn write prevention.

> **Note**
>
> Workloads that don't support torn write prevention have no performance impact. You don't need to make any changes for these workloads.
> Workloads that support torn write prevention, but are not configured to use it, continue to use the doublewrite buffer and don't receive any performance benefits.

To configure your MySQL or MariaDB software stack to disable the doublewrite buffer and use torn write prevention, complete the following steps:

1. Configure your volume to use ext4 file system with the BigAlloc option and set the cluster size to 4 KiB, 8 KiB, or 16 KiB. Using BigAlloc with a cluster size of 4 KiB, 8 KiB, or 16 KiB ensures that the file system allocates files that align with the respective boundary.

```
$  mkfs.ext4 -O bigalloc -C 4096|8192|16384 device_name
```

> **Note**
>
> For MySQL and MariaDB, you must use `-C 16384` to match the database page size. Setting allocation granularity to a value other than a multiple of the page size can result in allocations that might be mismatched with torn write prevention boundaries of the storage device.

For example:

```
$  mkfs.ext4 -O bigalloc -C 16384 /dev/nvme1n1
```

2. Configure InnoDB to use the `O_DIRECT` flushing method and turn off InnoDB doublewrite. Use your preferred text editor to open `/etc/my.cnf`, and update the `innodb_flush_method` and `innodb_doublewrite` parameters as follows:

```
innodb_flush_method=O_DIRECT
innodb_doublewrite=0
```

> **Important**
>
> If you are using Logical Volume Manager (LVM) or other storage virtualization layer, make sure that the starting offsets of the volumes are aligned on 16 KiB multiples. This is relative to the underlying NVMe storage to account for the metadata headers and superblocks used by the storage virtualization layer. If you add an offset to the LVM physical volume, it can cause misalignment between the file system allocations and the NVMe device's offsets, which would invalidate torn write prevention. For more information, see `--dataalignmentoffset` in the Linux manual page.

Application consistent Windows VSS based Amazon EBS snapshots

You can take application-consistent snapshots of all Amazon EBS volumes attached to your Amazon EC2 Windows instances using AWS Systems Manager Run Command. The snapshot

process uses the Windows Volume Shadow Copy Service (VSS) to take EBS volume level backups of VSS-aware applications. The snapshots include data from pending transactions between these applications and the disk. You don't have to shut down your instances or disconnect them when you need to back up all attached volumes.

There is no additional cost to use VSS based EBS snapshots. You only pay for EBS snapshots created by the backup process. For more information, see How am I billed for my Amazon EBS snapshots?

> **Note**
>
> Application consistent Windows VSS based snapshots are supported with Windows instances only.

Contents

- What is VSS?
- How the VSS based Amazon EBS snapshot solution works

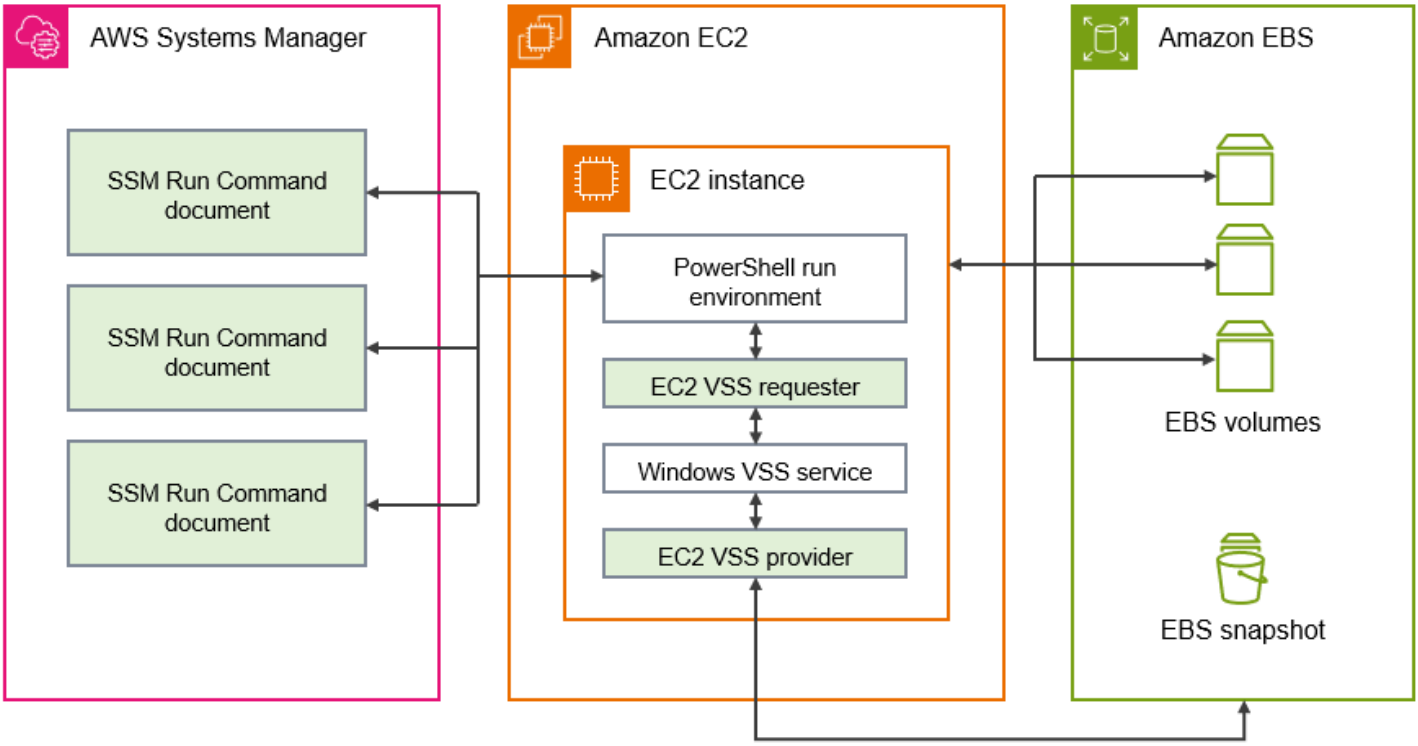
- Troubleshoot Windows VSS based EBS snapshots
- Use the AWS VSS solution to restore data for your instance
- AWS VSS solution version history

What is VSS?



Volume Shadow Copy Service (VSS) is a backup and recovery technology included in Microsoft Windows. It can create backup copies, or snapshots, of computer files or volumes while they are in use. For more information, see Volume Shadow Copy Service.

To create an application-consistent snapshot, the following software components are involved.

- *VSS service* — Part of the Windows operating system
- *VSS requester* — The software that requests the creation of shadow copies
- *VSS writer* — Typically provided as part of an application, such as SQL Server, to ensure a consistent data set to back up

- *VSS provider* — The component that creates the shadow copies of the underlying volumes

The Windows VSS based Amazon EBS snapshot solution consists of multiple Systems Manager (SSM) Run Command documents that facilitate backup creation, and a Systems Manager Distributor package, called `AwsVssComponents`, that includes an *EC2 VSS requester* and an *EC2 VSS provider*. The `AwsVssComponents` package must be installed on EC2 Windows instances to take application-consistent snapshots of EBS volumes. The following diagram illustrates the relationship between these software components.

How the VSS based Amazon EBS snapshot solution works

The process for taking application-consistent, VSS based EBS snapshot scripts consists of the following steps.

1. Complete the Prerequisites to create Windows VSS based EBS snapshots.
2. Enter parameters for the `AWSEC2-VssInstallAndSnapshot` SSM document and run this document by using Run Command. For more information, see Run the AWSEC2-VssInstallAndSnapshot command document (recommended).
3. The Windows VSS service on your instance coordinates all ongoing I/O operations for running applications.

4. The system flushes all I/O buffers and temporarily pauses all I/O operations. The pause lasts, at most, ten seconds.
5. During the pause, the system creates snapshots of all volumes attached to the instance.
6. The pause is lifted and I/O resumes operation.
7. The system adds all newly-created snapshots to the list of EBS snapshots. The system tags all VSS based EBS snapshots successfully created by this process with **AppConsistent:true**.
8. If you need to restore from a snapshot, you can use the standard EBS process of creating a volume from a snapshot, or you can restore all volumes to an instance by using a sample script, as described in Use the AWS VSS solution to restore data for your instance.

Prerequisites to create Windows VSS based EBS snapshots

You can create VSS based EBS snapshots with Systems Manager Run Command, AWS Backup, or Amazon Data Lifecycle Manager. The following prerequisites apply for all solutions.

System requirements

Ensure that your EC2 Windows instance meets all of the system requirements to create VSS based snapshots, including supported versions of the Windows operating system, .NET framework, PowerShell, AWS Tools for Windows PowerShell, and the AWS Systems Manager Agent.

IAM permissions

The IAM role that's attached to your Amazon EC2 Windows instance must have permission to create application-consistent snapshots with VSS. To grant the necessary permissions, you can attach the `AWSEC2VssSnapshotPolicy` managed policy to your instance profile.

VSS components

To create application-consistent snapshots on Windows operating systems, the `AwsVssComponents` package must be installed on the instance. The package contains an on-instance EC2 VSS Agent that functions as the VSS requester, and an EC2 VSS provider for EBS volumes.

System requirements

Install the Systems Manager Agent

VSS is orchestrated by the Systems Manager Agent using PowerShell. Ensure that you have installed SSM Agent version `3.0.502.0` or later on your EC2 instance. If you are already using an older version of the SSM Agent, update it using Run Command. For more information, see Setting up Systems Manager for Amazon EC2 instances and Working with SSM Agent on Amazon EC2 instances for Windows Server in the *AWS Systems Manager User Guide*.

Amazon EC2 Windows instance requirements

VSS based EBS snapshots are supported for instances running Windows Server 2016 and later.

.NET Framework version

The `AwsVssComponents` package requires .NET Framework version `4.6` or later. Windows operating system versions prior to Windows Server 2016 default to an earlier version of the .NET Framework. If your instance uses an earlier version of the .NET Framework, you must install version `4.6` or later using Windows Update.

AWS Tools for Windows PowerShell version

Ensure that your instance is running AWS Tools for Windows PowerShell version `3.3.48.0` or later. To check your version, run the following command in the PowerShell terminal on the instance.

```
C:\> Get-AWSPowerShellVersion
```

If you need to update AWS Tools for Windows PowerShell on your instance, see Installing the AWS Tools for Windows PowerShell in the *AWS Tools for PowerShell User Guide*.

Windows PowerShell version

Ensure that your instance is running Windows PowerShell major version 3, 4, or 5. To check your version, run the following command in a PowerShell terminal on the instance.

```
C:\> $PSVersionTable.PSVersion
```

PowerShell language mode

Ensure that your instance has the PowerShell language mode set to `FullLanguage`. For more information, see about_Language_Modes in the Microsoft documentation.

Use an IAM managed policy to grant permissions for VSS based snapshots

The AWSEC2VssSnapshotPolicy managed policy enables Systems Manager to perform the following actions on your Windows instance:

- Create and tag EBS snapshots
- Create and tag Amazon Machine Images (AMIs)
- Attach metadata, such as the device ID, to the default snapshot tags that VSS creates.

This topic covers permission details for the VSS managed policy, and how to attach it to your EC2 instance profile IAM role.

Contents

- AWSEC2VssSnapshotPolicy managed policy details
- Attach the VSS snapshot managed policy to your instance profile role

AWSEC2VssSnapshotPolicy managed policy details

An AWS managed policy is a standalone policy that Amazon provides for AWS customers. AWS managed policies are designed to grant permissions for common use cases. You can't change the permissions that are defined in AWS managed policies. However, you can copy the policy and use it as a baseline for a customer managed policy that is specific to your use case.

For more information about AWS managed policies, see AWS managed policies in the *IAM User Guide*.

To use the **AWSEC2VssSnapshotPolicy** managed policy, you can attach it to the IAM role that's attached to your EC2 Windows Instances. This policy enables the EC2 VSS solution to create and add tags to Amazon Machine Images (AMIs) and EBS Snapshots. To attach the policy, see Attach the VSS snapshot managed policy to your instance profile role.

Permissions granted by AWSEC2VssSnapshotPolicy

The **AWSEC2VssSnapshotPolicy** policy includes the following Amazon EC2 permissions to allow Amazon EC2 to create and manage VSS snapshots on your behalf. You can attach this managed policy to the IAM instance profile role that you use for your EC2 Windows instances.

- **ec2:CreateTags** – Add tags to EBS snapshots and AMIs to help identify and categorize the resources.

- **ec2:DescribeInstanceAttribute** – Retrieve the EBS volumes and corresponding block device mappings that are attached to the target instance.
- **ec2:CreateSnapshots** – Create snapshots of EBS volumes.
- **ec2:CreateImage** – Create an AMI from a running EC2 instance.
- **ec2:DescribeImages** – Retrieve the information for EC2 AMIs and snapshots.
- **ec2:DescribeSnapshots** – Determine the create time and status of snapshots to verify application consistency.

> **Note**
>
> To view permission details for this policy, see AWSEC2VssSnapshotPolicy in the *AWS Managed Policy Reference*.

Streamline permissions for specific use cases - advanced

The `AWSEC2VssSnapshotPolicy` managed policy includes permissions for all of the ways that you can create VSS based snapshots. You can create a custom policy that includes only the permissions that you need.

Use case: Create AMI, Use case: Use AWS Backup service

If you exclusively use the `CreateAmi` option, or if you create VSS based snapshots only through the AWS Backup service, then you can streamline the policy statements as follows.

- Omit policy statements identified by the following statement IDs (SIDs):
  - `CreateSnapshotsWithTag`
  - `CreateSnapshotsAccessInstance`
  - `CreateSnapshotsAccessVolume`
- Adjust the `CreateTagsOnResourceCreation` statement as follows:
  - Remove `arn:aws:ec2:*:*:snapshot/*` from the resources.
  - Remove `CreateSnapshots` from the `ec2:CreateAction` condition.
- Adjust the `CreateTagsAfterResourceCreation` statement to remove `arn:aws:ec2:*:*:snapshot/*` from the resources.

- Adjust the `DescribeImagesAndSnapshots` statement to remove `ec2:DescribeSnapshots` from the statement action.

Use case: Snapshot only

If you don't use the `CreateAmi` option, then you can streamline the policy statements as follows.

- Omit policy statements identified by the following statement IDs (SIDs):
  - `CreateImageAccessInstance`
  - `CreateImageWithTag`
- Adjust the `CreateTagsOnResourceCreation` statement as follows:
  - Remove `arn:aws:ec2:*:*:image/*` from the resources.
  - Remove `CreateImage` from the `ec2:CreateAction` condition.
- Adjust the `CreateTagsAfterResourceCreation` statement to remove `arn:aws:ec2:*:*:image/*` from the resources.
- Adjust the `DescribeImagesAndSnapshots` statement to remove `ec2:DescribeImages` from the statement action.

> **Note**
>
> To ensure that your customized policy performs as expected, we recommend that you regularly review and incorporate updates to the managed policy.

Attach the VSS snapshot managed policy to your instance profile role

To grant permissions for VSS based snapshots for your EC2 Windows instance, you can attach the **AWSEC2VssSnapshotPolicy** managed policy to your instance profile role as follows. It's important to ensure that your instance meets all System requirements.

> **Note**
>
> To use the managed policy, your instance must have the `AwsVssComponents` package version `2.3.1` or later installed. For version history, see AwsVssComponents package versions.

1. Open the IAM console at https://eusc-de-east-1.console.amazonaws-eusc.eu/iam/.
2. In the navigation pane, choose **Roles** to see a list of IAM roles that you have access to.
3. Select the **Role name** link for the role that's attached to your instance. This opens the role detail page.
4. To attach the managed policy, choose **Add permissions**, located in the upper right corner of the list panel. Then select **Attach policies** from the dropdown list.
5. To streamline results, enter the policy name in the search bar (`AWSEC2VssSnapshotPolicy`).
6. Select the checkbox next to the name of the policy to attach, and choose **Add permissions**.

Manage VSS components package for Windows VSS based EBS snapshots

Before you create VSS based EBS snapshots, ensure that you have the latest version of the VSS components package installed on your Windows instance. There are several ways that you can install the `AwsVssComponents` package onto an existing instance, as follows:

- (Recommended) Run the AWSEC2-VssInstallAndSnapshot command document (recommended). This automatically installs or updates if needed every time it runs.
- Manually install the VSS components on an EC2 Windows instance.
- Update the VSS components package on your EC2 Windows instance.

You can also create an AMI with EC2 Image Builder that uses the `aws-vss-components-windows` managed component to install the `AwsVssComponents` package for the image. The managed component uses AWS Systems Manager Distributor to install the package. After Image Builder creates the image, every instance that you launch from the associated AMI will have the VSS package installed on it. For more information about how you can create an AMI with the VSS package installed, see Distributor package managed components for Windows in the *EC2 Image Builder User Guide*.

Contents

- Manually install the VSS components on an EC2 Windows instance
- Update the VSS components package on your EC2 Windows instance

Manually install the VSS components on an EC2 Windows instance

Your EC2 Windows instance must have VSS components installed before you can create application-consistent snapshots with Systems Manager. If you don't run the `AWSEC2-VssInstallAndSnapshot` command document to automatically install or update the package every time you create application-consistent snapshots, you must manually install the package.

You must also install manually if you plan to use one of the following methods to create application-consistent snapshots from your EC2 instance.

- Create VSS snapshots using AWS Backup
- Create VSS snapshots using Amazon Data Lifecycle Manager

If you need to perform a manual install, we recommend that you use the latest AWS VSS component package to improve the reliability and performance of application-consistent snapshots on your EC2 Windows instances.

> **Note**
>
> To automatically install or update the `AwsVssComponents` package whenever you create application-consistent snapshots, we recommend that you use Systems Manager to run the `AWSEC2-VssInstallAndSnapshot` document. For more information, see Run the AWSEC2-VssInstallAndSnapshot command document (recommended).

To install the VSS components on an Amazon EC2 Windows instance, follow the steps for your preferred environment.

Console

To install the VSS components using SSM Distributor

1. Open the AWS Systems Manager console at https://eusc-de-east-1.console.amazonaws-eusc.eu/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Choose **Run command**.
4. For **Command document**, choose the button next to **AWS-ConfigureAWSPackage**.
5. For **Command parameters**, do the following:

a. Verify that **Action** is set to **Install**.

b. For **Name**, enter `AwsVssComponents`.

c. For **Version**, enter a version or leave the field empty so that Systems Manager installs the latest version.

6. For **Targets**, identify the instances on which you want to run this operation by specifying tags or selecting instances manually.

> **Note**
>
> If you choose to select instances manually, and an instance you expect to see is not included in the list, see Where Are My Instances? in the *AWS Systems Manager User Guide* for troubleshooting tips.

7. For **Other parameters**:

- (Optional) For **Comment**, type information about this command.
- For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

8. (Optional) For **Rate control**:

- For **Concurrency**, specify either a number or a percentage of instances on which to run the command at the same time.

> **Note**
>
> If you selected targets by choosing Amazon EC2 tags, and you are not certain how many instances use the selected tags, then limit the number of instances that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other instances after it fails on either a number or a percentage of instances. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Instances still processing the command might also send errors.

9. (Optional) For **Output options** section, if you want to save the command output to a file, select the box next to **Enable writing to an S3 bucket**. Specify the bucket and (optional) prefix (folder) names.

> **Note**
>
> The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the instance, not those of the user performing this task. For more information, see Configure EC2 instance permissions in the *AWS Systems Manager User Guide*.

10. (Optional) Specify options for **SNS notifications**.

    For information about configuring Amazon SNS notifications for Run Command, see Configuring Amazon SNS Notifications for AWS Systems Manager.

11. Choose **Run**.

AWS CLI

Use the following procedure to download and install the `AwsVssComponents` package on your instances by using Run Command from the AWS CLI. The package installs two components: a VSS requester and a VSS provider. The system copies these components to a directory on the instance, and then registers the provider DLL as a VSS provider.

To install the VSS package

Run the following command to download and install the required VSS components for Systems Manager.

```
aws ssm send-command \
    --document-name "AWS-ConfigureAWSPackage" \
    --instance-ids "i-1234567890abcdef0" \
    --parameters '{"action":["Install"],"name":["AwsVssComponents"]}'
```

PowerShell

Use the following procedure to download and install the `AwsVssComponents` package on your instances by using Run Command from the Tools for Windows PowerShell. The package installs two components: a VSS requester and a VSS provider. The system copies these components to a directory on the instance, and then registers the provider DLL as a VSS provider.

To install the VSS package

Run the following command to download and install the required VSS components for Systems Manager.

```
Send-SSMCommand `
    -DocumentName "AWS-ConfigureAWSPackage" `
    -InstanceId "i-1234567890abcdef0" `
    -Parameter @{'action'='Install';'name'='AwsVssComponents'}
```

Verify the signature on AWS VSS components

Use the following procedure to verify the signature on the `AwsVssComponents` package.

1. Connect to your Windows instance. For more information, see Connect to your Windows instance using RDP.
2. Navigate to C:\Program Files\Amazon\AwsVssComponents.
3. Open the context (right-click) menu for `ec2-vss-agent.exe`, and then choose **Properties**.
4. Navigate to the **Digital Signatures** tab and verify that the name of the signer is Amazon Web Services Inc.
5. Use the preceding steps to verify the signature on `Ec2VssInstaller` and `Ec2VssProvider.dll`.

Update the VSS components package on your EC2 Windows instance

We recommend that you keep the VSS components updated with the latest recommended version. There are several different ways that you can update components when a new version of the `AwsVssComponents` package is released.

Update methods

- You can repeat the steps described in Manually install the VSS components on an EC2 Windows instance when a new version of the AWS VSS components is released.
- You can configure a Systems Manager State Manager association to automatically download and install new or updated VSS components when the `AwsVssComponents` package becomes available.
- You can automatically install or update the `AwsVssComponents` package whenever you create application-consistent snapshots, when you use Systems Manager to run the `AWSEC2-VssInstallAndSnapshot` document.

> **Note**
>
> We recommend that you use Systems Manager to run the `AWSEC2-VssInstallAndSnapshot` command document, which automatically installs or updates the `AwsVssComponents` package before it creates the application-consistent snapshots. For more information, see Run the AWSEC2-VssInstallAndSnapshot command document (recommended).

To create a Systems Manager State Manager association, follow the steps for your preferred environment.

Console

When you create a Systems Manager State Manager association, there are two options for updating the `AwsVssComponents` package, as follows:

Uninstall and reinstall

This method downloads and installs the package with no additional prerequisites.

In-place update

This performs an in-place update for the package, and has the following prerequisites:

- The SSM Agent version that's installed on the instance must be version `3.3.808.0` or later. For more information, see Working with SSM Agent on EC2 instances for Windows Server in the *AWS Systems Manager User Guide*.
- If specified, the `AwsVssComponents` package version must be version `2.5.0` or later. Earlier versions don't support in-place update.

> **Note**
>
> if your instance doesn't meet these prerequisites, in-place update will fail. Use the **Uninstall and reinstall** option instead.

To create a State Manager association

1. Open the AWS Systems Manager console at https://eusc-de-east-1.console.amazonaws-eusc.eu/systems-manager/.

2. In the navigation pane, choose **State Manager**.

   Or, if the Systems Manager homepage opens first, open the navigation pane and then choose **State Manager**.

3. Choose **Create association**.
4. In the **Name** field, enter a descriptive name.
5. In the **Document** list, choose **AWS-ConfigureAWSPackage**.
6. In the **Parameters** section, choose **Install** from the **Action** list.
7. For **Installation type**, choose either **Uninstall and reinstall** or **In-place update**.
8. In the **Name** field, enter `AwsVssComponents`. You can keep the **Version** and **Additional Arguments** fields empty.
9. In the **Targets** section, choose an option.

   > **Note**
   >
   > If you choose to target instances by using tags, and you specify tags that map to Linux instances, the association succeeds on the Windows instance but fails on the Linux instances. The overall status of the association shows **Failed**.

10. In the **Specify schedule** section, choose an option.
11. In the **Advanced options** section, for **Compliance severity**, choose a severity level for the association. For more information, see Learn about association compliance. For **Change Calendars**, select a preconfigured change calendar. For more information, see about AWS Systems Manager Change Calendar.
12. For **Rate control**, do the following:

    - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.
    - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes.

13. (Optional) For **Output options**, to save the command output to a file, select **Enable writing output to S3**. Enter the bucket and prefix (folder) names in the boxes.
14. Choose **Create association**, and then choose **Close**. The system attempts to create the association on the instances and immediately apply the state.

> **Note**
>
> If EC2 instances for Windows Server show a status of **Failed**, verify that the SSM Agent is running on the instance, and verify that the instance is configured with an AWS Identity and Access Management (IAM) role for Systems Manager. For more information, see Setting up AWS Systems Manager.

AWS CLI

Use the create-association command to update a Distributor package on a schedule without taking the associated application offline. Only new or updated files in the package are replaced.

To create a State Manager association

Run the following command to create an association. The value of `--name`, the document name, is always `AWS-ConfigureAWSPackage`. The following command uses the key `InstanceIds` to specify target instances.

```
aws ssm create-association \
    --name "AWS-ConfigureAWSPackage" \
    --parameters action=Install,installationType="Uninstall and
 reinstall",name=AwsVssComponents \
    --targets Key=InstanceIds,Values=i-1234567890abcdef0,i-000011112222abcde
```

PowerShell

To create a State Manager association

Use the New-SSMAssociation cmdlet.

```
New-SSMAssociation `
    -Name "AWS-ConfigureAWSPackage" `
    -Parameter  @{
        "action" = "Install"
        "installationType" = "Uninstall and reinstall"
        "name" = "AwsVssComponents"
    } `
    -Target @{
        "Key" = "InstanceIds"
        "Values" = @("i-1234567890abcdef0", "i-000011112222abcde")
```

```
}
```

Create VSS based EBS snapshots for your EC2 Windows instance

After you've met all of the Prerequisites to create Windows VSS based EBS snapshots, you can use any of the following methods to create VSS based snapshots from your EC2 instance.

AWS Systems Manager command documents

Use Systems Manager command documents to create VSS based snapshots.

To automate backups, you can create an AWS Systems Manager maintenance window task that uses the `AWSEC2-VssInstallAndSnapshot` command document. For more information, see Working with Maintenance Windows (Console) in the *AWS Systems Manager User Guide*.

AWS Backup

You can create a VSS backup when using AWS Backup by enabling VSS in the console or CLI. For more information, see Creating Windows VSS backups in the *AWS Backup Developer Guide*.

> **Note**
>
> AWS Backup doesn't automatically install the `AwsVssComponents` package on your instance. You must perform a manual install on your instance. For more information, see Manually install the VSS components on an EC2 Windows instance.

Amazon Data Lifecycle Manager

You can create VSS snapshots using Amazon Data Lifecycle Manager by enabling pre and post scripts in your snapshot lifecycle policies. For more information, see Automating application-consistent snapshots in the *Amazon EBS User Guide*.

> **Note**
>
> Amazon Data Lifecycle Manager doesn't automatically install the `AwsVssComponents` package on your instance. You must perform a manual install on your instance. For more information, see Manually install the VSS components on an EC2 Windows instance.

Use Systems Manager command documents to create VSS based snapshots

You can use AWS Systems Manager command documents to create VSS based snapshots. The following content introduces the command documents that are available, and the runtime parameters that the documents use to create your snapshots.

Before you use any of the Systems Manager command documents, ensure that you've met all Prerequisites to create Windows VSS based EBS snapshots.

Topics

- Parameters for Systems Manager VSS snapshot documents
- Run Systems Manager VSS snapshot command documents

Parameters for Systems Manager VSS snapshot documents

The Systems Manager documents that create VSS snapshots all use the following parameters, except where noted:

AmiName (string, optional)

If the **CreateAmi** option is set to `True`, specify the name of the AMI that the backup creates.

description (string, optional)

Specify a description for the snapshots or image that this process creates.

CollectDiagnosticLogs (string, optional)

To collect more information during snapshot and AMI creation steps, set this parameter to "`True`". The default value for this parameter is "`False`". Consolidated diagnostic logs are saved as a `.zip` format archive at the following location on your instance:

`C:\ProgramData\Amazon\AwsVss\Logs\`*`timestamp`*`.zip`

CopyOnly (string, optional)

If you use the native SQL Server backup in addition to AWS VSS, performing a Copy-only backup prevents AWS VSS from breaking the native differential backup chain. To perform a Copy-only backup operation, set this parameter to `True`.

The default value for this parameter is `False`, which causes AWS VSS to perform a full backup operation.

CreateAmi (string, optional)

To create a VSS based Amazon Machine Image (AMI) to back up your instance, set this parameter to `True`. The default value for this parameter is `False`, which backs up your instance with an EBS snapshot instead.

For more information about creating an AMI from an instance, see Create an Amazon EBS-backed AMI.

executionTimeout (string, optional)

Specify the maximum time in seconds to run the snapshot creation process on the instance, or to create an AMI from the instance. Increasing this timeout allows the command to wait longer for VSS to start its freeze and complete tagging of the resources it creates. This timeout only applies to the snapshot or AMI creation steps. The initial step to install or update the `AwsVssComponents` package is not included in the timeout.

ExcludeBootVolume (string, optional)

This setting excludes boot volumes from the backup process if you create snapshots. To exclude boot volumes from your snapshots, set **ExcludeBootVolume** to `True`, and **CreateAmi** to `False`.

If you create an AMI for your backup, this parameter should be set to `False`. The default value for this parameter is `False`.

NoWriters (string, optional)

To exclude application VSS writers from the snapshot process, set this parameter to `True`. Excluding application VSS writers can help you resolve conflicts with third-party VSS backup components. The default value for this parameter is `False`.

If `SaveVssMetadata` is `True`, this parameter must be set to `False`.

SaveVssMetadata (string, optional)

To save VSS metadata files during every snapshot, set this parameter to `True`. The default value is `False`. These files help provide insights into which components or writers were included in a backup operation, and the associated files and volumes for each snapshot. The metadata files are used when restoring a SQL database using VSS restore solution. For more information on how to restore a SQL database from VSS snapshots, see Use an automation runbook to restore your database from AWS VSS solution snapshots.

Metadata files have the associated snapshot set id in their names. You can find them at the following location on your instance:

```
C:\ProgramData\Amazon\AwsVss\VssMetadata\
```

Warning

- Saving VSS metadata files requires `AwsVssComponents` package version 2.4.0 or later. If your instance has an earlier version installed, setting `SaveVssMetadata` to `True` causes the snapshot creation to fail.
- The `NoWriters` and `SaveVssMetadata` parameters are mutually exclusive. If both are set to `True` then snapshot creation fails.

tags (string, optional)

We recommend that you tag your snapshots and images to help you locate and manage your resources, for example, to restore volumes from a list of snapshots. The system adds the `Name` key, with a blank value where you can specify the name that you want to apply to your output snapshots or images.

If you want to specify additional tags, separate tags with a semicolon in between. For example, `Key=Environment,Value=Test;Key=User,Value=TestUser1`.

Note

Tag keys and values must only contain alphanumeric characters and the following special characters: `( ) ./\-"'@_+:={}`.

By default, the system adds the following reserved tags for VSS based snapshots and images.

- **Device** – For VSS based snapshots, this is the device name of the EBS volume that the snapshot captures.
- **AppConsistent** – This tag indicates the successful creation of a VSS based snapshot or AMI.
- **AwsVssConfig** – This identifies snapshots and AMIs that are created with VSS enabled. The tag includes meta information such as the `AwsVssComponents` version, and the Snapshot Set ID.

> **Warning**
>
> Specifying any of these reserved tags in your parameter list will cause an error.

VssVersion (string, optional)

For the `AWSEC2-VssInstallAndSnapshot` document only, you can specify the `VssVersion` parameter to install a specific version of `AwsVssComponents` package on your instance. Leave this parameter blank to install the recommended default version.

If the specified version of the `AwsVssComponents` package is already installed, the script skips the install step and moves on to the backup step. For a list of `AwsVssComponents` package versions and operating support, see AWS VSS solution version history.

Run Systems Manager VSS snapshot command documents

You can create VSS based EBS snapshots with AWS Systems Manager command documents as follows.

Run the AWSEC2-VssInstallAndSnapshot command document (recommended)

When you use AWS Systems Manager to run the `AWSEC2-VssInstallAndSnapshot` document, the script runs the following steps.

1. The script first installs or updates the `AwsVssComponents` package on your instance, depending on whether it's already installed.
2. The script creates the application-consistent snapshots after the first step completes.

To run the `AWSEC2-VssInstallAndSnapshot` document, follow the steps for your preferred environment.

Console

Create VSS based EBS snapshots from the console

1. Open the AWS Systems Manager console at https://eusc-de-east-1.console.amazonaws-eusc.eu/systems-manager/.

2. Select **Run Command** from the navigation pane. This shows a list of commands that are currently running in your account, if applicable.
3. Choose **Run command**. This opens a list of command documents that you have access to.
4. Select `AWSEC2-VssInstallAndSnapshot` from the list of command documents. To streamline results, you can enter all or part of the document name. You can also filter by the owner, by platform types, or by tags.

   When you select a command document, details populate below the list.
5. Select `Default version at runtime` from the **Document version** list.
6. Configure the **Command parameters** to define how `AWSEC2-VssInstallAndSnapshot` will install the `AwsVssComponents` package and back up with VSS snapshots or an AMI. For parameter details, see Parameters for Systems Manager VSS snapshot documents.
7. For **Target selection**, specify tags or select instances manually to identify the instances on which to run this operation.

   > **Note**
   >
   > If you select instances manually, and an instance you expect to see is not included in the list, see Where Are My Instances? for troubleshooting tips.
8. For additional parameters to define Systems Manager Run Command behavior such as **Rate control**, enter values as described in Running commands from the console.
9. Choose **Run**.

   If successful, the command populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the Systems Manager command output for details about why the execution failed. If the command successfully completed, but a specific volume backup failed, you can troubleshoot the failure in the list of EBS volumes.

AWS CLI

You can run the following commands in the AWS CLI to create VSS based EBS snapshots and get the status of your snapshot creation.

Create VSS based EBS snapshots

Run the following command to create VSS based EBS snapshots. To create the snapshots, you must identify the instances with the `--instance-ids` parameter. For more information about other parameters that you can use, see Parameters for Systems Manager VSS snapshot documents.

```
aws ssm send-command \
 --document-name "AWSEC2-VssInstallAndSnapshot" \
 --instance-ids "i-01234567890abcdef" \
 --parameters '{"ExcludeBootVolume":["False"],"description":["Description"],"tags":
["Key=key_name,Value=tag_value"],"VssVersion":[""]}'
```

If successful, the command document populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the command output for details about why the execution failed.

Get command status

To get the current status of the snapshots, run the following command using the command ID returned from **send-command**.

```
aws ssm get-command-invocation
 --instance-ids "i-01234567890abcdef" \
 --command-id "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111" \
 --plugin-name "CreateVssSnapshot"
```

PowerShell

Run the following commands with AWS Tools for Windows PowerShell to create VSS based EBS snapshots and get the current runtime status for the creation of your output. Specify parameters described in the prior list to modify the behavior of the snapshot process.

Create VSS based EBS snapshots with Tools for Windows PowerShell

Run the following command to create VSS based EBS snapshots or AMIs.

```
Send-SSMCommand -DocumentName "AWSEC2-VssInstallAndSnapshot" -InstanceId
 "i-01234567890abcdef" -Parameter
 @{'ExcludeBootVolume'='False';'description'='a_description'
 ;'tags'='Key=key_name,Value=tag_value';'VssVersion'=''}
```

Get command status

To get the current status of the snapshots, run the following command using the command ID returned from **Send-SSMCommand**.

```
Get-SSMCommandInvocationDetail -InstanceId "i-01234567890abcdef" -CommandId
 "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111" -PluginName "CreateVssSnapshot"
```

If successful, the command populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the command output for details about why the execution failed.

Run the AWSEC2-CreateVssSnapshot command document

To run the `AWSEC2-CreateVssSnapshot` document, follow the steps for your preferred environment.

Console

Create VSS based EBS snapshots from the console

1. Open the AWS Systems Manager console at https://eusc-de-east-1.console.amazonaws-eusc.eu/systems-manager/.
2. Select **Run Command** from the navigation pane. This shows a list of commands that are currently running in your account, if applicable.
3. Choose **Run command**. This opens a list of command documents that you have access to.
4. Select `AWSEC2-CreateVssSnapshot` from the list of command documents. To streamline results, you can enter all or part of the document name. You can also filter by the owner, by platform types, or by tags.

   When you select a command document, details populate below the list.
5. Select `Default version at runtime` from the **Document version** list.
6. Configure the **Command parameters** to define how `AWSEC2-CreateVssSnapshot` will back up with VSS snapshots or an AMI. For parameter details, see Parameters for Systems Manager VSS snapshot documents.
7. For **Target selection**, specify tags or select instances manually to identify the instances on which to run this operation.

> **Note**
>
> If you select instances manually, and an instance you expect to see is not included in the list, see Where Are My Instances? for troubleshooting tips.

8. For additional parameters to define Systems Manager Run Command behavior such as **Rate control**, enter values as described in Running commands from the console.
9. Choose **Run**.

   If successful, the command populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the Systems Manager command output for details about why the execution failed. If the command successfully completed, but a specific volume backup failed, you can troubleshoot the failure in the list of EBS volumes.

AWS CLI

You can run the following command in the AWS CLI to create VSS based EBS snapshots.

Create VSS based EBS snapshots

Run the following command to create VSS based EBS snapshots. To create the snapshots, you must identify the instances with the `--instance-ids` parameter. For more information about other parameters that you can use, see Parameters for Systems Manager VSS snapshot documents.

```
aws ssm send-command \
 --document-name "AWSEC2-CreateVssSnapshot" \
 --instance-ids "i-01234567890abcdef" \
 --parameters '{"ExcludeBootVolume":["False"],"description":["Description"],"tags":
["Key=key_name,Value=tag_value"]}'
```

If successful, the command document populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the command output for details about why the execution failed.

PowerShell

Run the following command with AWS Tools for Windows PowerShell to create VSS based EBS snapshots.

Create VSS based EBS snapshots with Tools for Windows PowerShell

Run the following command to create VSS based EBS snapshots. To create the snapshots, you must identify the instances with the `InstanceId` parameter. You can specify more than one instance to create snapshots for. For more information about other parameters that you can use, see Parameters for Systems Manager VSS snapshot documents.

```
Send-SSMCommand -DocumentName AWSEC2-CreateVssSnapshot -InstanceId
 "i-01234567890abcdef" -Parameter
 @{'ExcludeBootVolume'='False';'description'='a_description'
 ;'tags'='Key=key_name,Value=tag_value'}
```

If successful, the command populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the command output for details about why the execution failed. If the command successfully completed, but a specific volume backup failed, you can troubleshoot the failure in the list of EBS snapshots.

Run command documents for a Windows Failover Cluster with shared EBS storage

You can use any of the command line procedures described in the previous section to create a VSS based snapshot. The command document (`AWSEC2-VssInstallAndSnapshot` or `AWSEC2-CreateVssSnapshot`) must run on the primary node in your cluster. The document will fail on the secondary nodes as they don't have access to the shared disks. If your primary and secondary change dynamically, you can run the AWS Systems Manager Run Command document on multiple nodes with the expectation that the command will succeed on the primary node and fail on secondary nodes.

Note

To automate backups, you can create an AWS Systems Manager maintenance window task that uses the `AWSEC2-VssInstallAndSnapshot` document. For more information, see Working with Maintenance Windows (Console) in the *AWS Systems Manager User Guide*.

Troubleshoot Windows VSS based EBS snapshots

Before you try any other troubleshooting steps, we recommend that you verify the following details.

- Ensure that you've met all Prerequisites to create Windows VSS based EBS snapshots.
- Verify that you're using the latest Windows OS version support of the `AwsVssComponents` package for your operating system. The issue that you've observed might have been addressed in newer versions.

Topics

- Check log files
- Collect additional diagnostic logs
- Use VSS on instances with proxy configured
- Error: Thaw pipe connection timed out, error on thaw, timeout waiting for VSS Freeze, or other timeout errors
- Error: Cannot invoke method. Method invocation is supported only on core types in this language mode

Check log files

If you experience problems or receive error messages when you create VSS based EBS snapshots, you can view the command output in the Systems Manager console.

For Systems Manager documents that create VSS snapshots, you can set the `CollectDiagnosticLogs` parameter to "`True`" at runtime. When the `CollectDiagnosticLogs` parameter is set to "`True`", VSS collects additional logs to aid in debugging. For more information, see Collect additional diagnostic logs.

If you collect diagnostic logs, the Systems Manager document stores them on your instance at the following location: `C:\ProgramData\Amazon\AwsVss\Logs\`*`timestamp`*`.zip`. The default for the `CollectDiagnosticLogs` parameter is "`False`".

> **Note**
>
> For additional debugging help, you can send the `.zip` file to Support.

The following additional logs are available, whether you collect diagnostic logs or not:

- `%ProgramData%\Amazon\SSM\InstanceData\`*`InstanceID`*`\document\orchestration\`*`SSMCommandID`*`\awsrunPowerShellScript\runPowerShellScript\stdout`
- `%ProgramData%\Amazon\SSM\InstanceData\`*`InstanceID`*`\document\orchestration\`*`SSMCommandID`*`\awsrunPowerShellScript\runPowerShellScript\stderr`

You can also open the Event Viewer Windows application and choose **Windows Logs**, **Application** to view additional logs. To see events specifically from the EC2 Windows VSS Provider and the Volume Shadow Copy Service, filter by **Source** on the terms **`Ec2VssSoftwareProvider`** and **`VSS`**.

If you're using Systems Manager with VPC endpoints, and the Systems Manager send-command API action (**Run Command** in the console) failed, verify that you configured the following endpoint correctly: **com.amazonaws.*region*.ec2**.

Without the Amazon EC2 endpoint defined, the call to enumerate attached EBS volumes fails, which causes the Systems Manager command to fail. For more information about setting up VPC endpoints with Systems Manager, see Create a Virtual Private Cloud Endpoint in the *AWS Systems Manager User Guide*.

Collect additional diagnostic logs

To collect additional diagnostic logs when you use the Systems Manager send command to run the VSS snapshot document, set the `CollectDiagnosticLogs` input parameter to "`True`" at runtime. We recommend that you set this parameter to "`True`" when you troubleshoot.

To see a command line example, select one of the following tabs.

AWS CLI

The following example runs the `AWSEC2-CreateVssSnapshot` Systems Manager document in the AWS CLI:

```
aws ssm send-command \
    --document-name "AWSEC2-CreateVssSnapshot" \
    --instance-ids "i-1234567890abcdef0" \
    --parameters '{"description":["Example - create diagnostic logs at
 runtime."],"tags":["Key=tag_name,Value=tag_value"],"CollectDiagnosticLogs":
["True"]}'
```

PowerShell

The following example runs the `AWSEC2-CreateVssSnapshot` Systems Manager document in PowerShell:

```
Send-SSMCommand `
    -DocumentName "AWSEC2-CreateVssSnapshot" `
    -InstanceId "i-1234567890abcdef0" `
    -Parameter @{'description'='Example - create diagnostic logs at
 runtime.';'tags'='Key=tag_name,Value=tag_value';'CollectDiagnosticLogs'='True'}
```

Use VSS on instances with proxy configured

If you experience problems when creating VSS based EBS snapshots on instances that use a proxy to reach EC2 endpoints, verify the following settings on your instance:

- Verify that the proxy is configured so that the EC2 service endpoints in the instance's Region and IMDS are reachable by AWS Tools for Windows PowerShell running as SYSTEM.
- To support using the system configured WinHTTP proxy, make sure that you've installed the latest `AwsVssComponents` version on your instance. For more information about configuring WinHTTP proxy, see Netsh Commands for Windows Hypertext Transfer Protocol (WINHTTP) on the Microsoft website.

Error: Thaw pipe connection timed out, error on thaw, timeout waiting for VSS Freeze, or other timeout errors

The EC2 Windows VSS Provider might time out due to activity or services on the instance preventing VSS based snapshots from proceeding in a timely manner. The Windows VSS Framework provides a non-configurable 10-second window during which communication to the file system is paused. During this time, `AWSEC2-CreateVssSnapshot` snapshots your volumes.

The following issues can cause the EC2 Windows VSS Provider to run into time limits during a snapshot:

- Excessive I/O to a volume
- Slow responsiveness of the EC2 API on the instance
- Fragmented volumes

- Incompatibility with some antivirus software
- Issues with a VSS Application writer
- When Module Logging is enabled for a large number of PowerShell modules, that can cause PowerShell scripts to run slowly

Most timeout issues that occur when you run the `AWSEC2-CreateVssSnapshot` command document are related to the workload on the instance being too high at the time of the backup. The following actions can help you take a successful snapshot:

- Retry the `AWSEC2-CreateVssSnapshot` command to see if the snapshot attempt is successful. If retrying succeeds in some cases, reducing the instance load might make snapshots more successful.
- Wait a while for the workload on the instance to decrease, and retry the `AWSEC2-CreateVssSnapshot` command. Alternatively, you can attempt snapshots when the instance is known to be under low stress.
- Attempt VSS snapshots when the antivirus software on the system is turned off. If this resolves the issue, refer to the antivirus software instructions and configure it to allow VSS snapshots.
- If there is a high volume of Amazon EC2 API calls in your account within the same Region where you're running a snapshot, API throttling might delay snapshot operations. To reduce throttling impact, use the latest `AwsVssComponents` package. This package uses the EC2 `CreateSnapshots` API action to reduce the number of mutating actions like per-volume snapshot creation and tagging.
- If you have multiple `AWSEC2-CreateVssSnapshot` command scripts running at the same time, you can take the following steps to reduce concurrency issues.
  - Consider scheduling snapshots during periods of lower API activity.
  - If you use **Run Command** in the Systems Manager console (or **SendCommand** in the API) to run the command script, you can use Systems Manager rate controls to reduce concurrency.

    You can also use Systems Manager rate controls to reduce concurrency for services like AWS Backup that use Systems Manager to run the command script.
- Run the command `vssadmin list writers` in a shell and see if it reports any errors in the **Last error** field for any writers on the system. If any writers report a **time out** error, consider retrying snapshots when the instance is under less load.

- When you use smaller instance types like *t2 | t3 | t3a*.nano or *t2 | t3 | t3a*.micro, timeouts due to memory and CPU constraints can occur. The following actions might help reduce timeout issues.
  - Try closing memory or CPU intensive applications before taking snapshots.
  - Try taking snapshots during periods of lower instance activity.

Error: Cannot invoke method. Method invocation is supported only on core types in this language mode

You will encounter this error when the PowerShell language mode is not set to `FullLanguage`. The `AWSEC2-CreateVssSnapshot` SSM document requires PowerShell to be configured to `FullLanguage` mode.

To verify the language mode, run the following command on the instance in a PowerShell console:

```
$ExecutionContext.SessionState.LanguageMode
```

For more information about language modes, see about_Language_Modes in the Microsoft documentation.

Use the AWS VSS solution to restore data for your instance

You can restore EBS volumes for a Windows instance from VSS based snapshots created by the AWS VSS solution. If your AWS VSS solution snapshots contain backups of a Microsoft SQL Server database, you can restore the database using the `AWSEC2-RestoreSqlServerDatabaseWithVss` AWS Systems Manager Automation runbook.

The database restore runbook automates the entire restore process, including creating volumes from the snapshots and attaching them to the instance. The automation leverages VSS technology to restore the database, allowing you to restore without stopping your SQL Server application or disconnecting any active connections.

For detailed instructions on how to use the Microsoft SQL Server database runbook, see Restore from VSS based snapshots in the *Microsoft SQL Server on Amazon EC2 User Guide*.

Customize a script to restore EBS volumes from AWS VSS solution snapshots

You can use the `RestoreVssSnapshotSampleScript.ps1` script as a model to create your own custom script that restores EBS volumes from AWS VSS solution snapshots. The sample script performs the following tasks:

- Stops an instance
- Removes all existing drives from the instance (except the boot volume, if it was excluded)
- Creates new volumes from the snapshots
- Attaches the volumes to the instance by using the device ID tag on the snapshot
- Restarts the instance

> **Important**
>
> The following script detaches all volumes attached to an instance, and then creates new volumes from a snapshot. Make sure that you have properly backed-up the instance. The old volumes are not deleted. If you want, you can edit the script to delete the old volumes.

To restore volumes from VSS based EBS snapshots

1. Download the RestoreVssSnapshotSampleScript.zip file and extract the file contents.
2. Open `RestoreVssSnapshotSampleScript.ps1` in a text editor and edit the sample call at the bottom of the script with a valid EC2 instance ID and EBS snapshot ID, and then run the script from PowerShell.

AWS VSS solution version history

This page includes release notes by version for the AWS VSS component package, as well as component and script version requirements for each supported version of Windows Server.

Topics

- AwsVssComponents package versions
- Windows OS version support

AwsVssComponents package versions

The following table describes the released versions of the AWS VSS component package.

Version	Details	Release date	Downloadable
2.5.2	• Added support for the `aws-eusc` partition endpoint. • Updated AWS SDK to incorporate security updates.	September 2, 2026	Yes
2.5.1	Fixed a case where SQL database restoration could fail when the target database parameter is specified.	March 13, 2025	Yes
2.5.0	• Added the capability to read VSS metadata files and restore a Microsoft SQL Server database on the instance. For more information, see Restore from VSS based snapshots in the *Microsoft SQL Server on Amazon EC2 User Guide*. • Added support for the in-place update option when installing or upgrading the `AwsVssComponents` package.	January 17, 2025	Yes
2.4.0	Added the capability to save VSS metadata files on snapshot creation. To enable this feature, see SaveVssMetadata in Parameters for Systems Manager VSS snapshot documents.	October 7, 2024	Yes
2.3.3	Updated the VSS agent to ensure that the `Ec2VssProvider` is used during snapshot creation.	June 25, 2024	Yes

Version	Details	Release date	Downloadable
2.3.2	Fixed a case where VSS provider registration is not removed on uninstallation.	May 9, 2024	Yes
2.3.1	Added new default tag `AwsVssConfig` to identify snapshots and AMIs created by AWS VSS.	March 7, 2024	Yes
2.2.1	• Added support for using the `DescribeInstanceAttribute` API. • Bug fixes and reliability improvements. • Deprecated support for Windows Server 2012 and 2012 R2. AWS VSS components version 2.2.1 installation on Windows Server 2012 and 2012 R2 will fail. AWS VSS components version 2.1.0 is the last version to support Windows Server 2012 and 2012 R2.	January 18, 2024	Yes
2.1.0	Added support for using the `CreateSnapshots` API.	November 6, 2023	Yes
2.0.1	Added support for using the WinHTTP proxy settings.	October 26, 2023	No
2.0.0	Added capability to the AWS VSS component to create snapshots and AMIs, which enables compatibility with PowerShell module logging, script block logging, and transcription features.	April 28, 2023	No

Version	Details	Release date	Downloadable
1.3.2.0	Fixed a case where installation failure is not reported correctly.	May 10, 2022	No
1.3.1.0	• Fixed snapshots failing on domain controllers in relation to an NTDS VSS writer logging error. • Fixed VSS agent error when uninstalling version 1.0 VSS provider.	February 6, 2020	Yes
1.3.00	• Improved logging by reducing unwanted verbosity. • Fixed regionalization issues during installation. • Fixed return codes for some provider registration error conditions. • Fixed various installation issues.	March 19, 2019	No
1.2.00	• Added command line parameters `-nw` (no-writers) and `-copy` (copy-only) to agent. • Fixed EventLog errors caused by improper memory allocation calls.	November 15, 2018	No
1.1	Fixed AWS VSS components that were being used incorrectly as the default Windows Backup and Restore provider.	December 12, 2017	No
1.0	Initial release.	November 20, 2017	No

Windows OS version support

The following table shows which AWS VSS solution versions you should run on each version of Windows Server on Amazon EC2.

Windows Server version	AwsVssComponents version	AWSEC2-VssInstallAndSnapshot version name	AWSEC2-CreateVssSnapshot version name
Windows Server 2025	default	default	default
Windows Server 2022	default	default	default
Windows Server 2019	default	default	default
Windows Server 2016	default	default	default
Windows Server 2012 R2	2.1.0	not supported	2012R2
Windows Server 2012	2.1.0	not supported	2012R2

Windows Server version	AwsVssComponents version	AWSEC2-VssInstallAndSnapshot version name	AWSEC2-CreateVssSnapshot version name
Windows Server 2008 R2	1.3.1.0	not supported	2008R2

Object storage, file storage, and file caching on Amazon EC2

Cloud file storage is a method for storing data in the cloud that provides servers and applications access to data through shared file systems. This compatibility makes cloud file storage ideal for workloads that rely on shared file systems and provides simple integration without code changes.

There are many file storage solutions that exist, ranging from a single node file server on a compute instance using block storage as the underpinnings with no scalability or few redundancies to protect the data, to a do-it-yourself clustered solution, to a fully-managed solution. The following content introduces some of the storage services provided by AWS for use with Amazon EC2 instances.

Contents

- Use Amazon S3 with Amazon EC2 instances
- Use Amazon EFS with Amazon EC2 Linux instances
- Use Amazon FSx with Amazon EC2 instances
- Use Amazon File Cache with Amazon EC2 instances

Use Amazon S3 with Amazon EC2 instances

Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance. You can use Amazon S3 to store and retrieve any amount of data for a range of use cases, such as data lakes, websites, backups, and big data analytics, from an Amazon EC2 instance or from anywhere over the internet. For more information, see What is Amazon S3?

There are two ways to access Amazon S3 data from your Amazon EC2 instances:

- **File access** – Use Amazon S3 Files to mount an S3 bucket as a high performance file system on your instance.
- **Object access** – Use the Amazon S3 API, AWS CLI, AWS SDKs, or tools like wget to copy objects to and from S3.

File access with Amazon S3 Files

Amazon S3 Files is a serverless file system that lets you mount your S3 general purpose bucket as a high performance file system on your compute instance. With S3 Files, you can access your S3 objects as files by using standard file system operations such as read and write on the local mount path.

You can mount an S3 file system to an EC2 instance either at launch, or after launch on a running instance.

Prerequisites

Before you set up S3 Files with your EC2 instance, make sure you have the following:

- An S3 file system and at least one mount target in the available state. For information about creating an S3 file system, see Working with Amazon S3 Files in the *Amazon S3 User Guide*.
- An EC2 Linux instance with an instance profile attached to it. For information about the required permissions to mount the file system, see IAM roles and policies in the *Amazon S3 User Guide*.
- Security groups that allow NFS traffic (port 2049) between your instance and the file system's mount targets. For information about the required security group settings, see Security groups in the *Amazon S3 User Guide*.

To mount a file system to an EC2 instance at launch using the EC2 console

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. Choose **Launch instance**.
3. Under **Network settings**, do the following:
    a. Choose **Edit**.
    b. For **Subnet**, select a subnet.

c. Select the default security group to make sure that your EC2 instance can access your S3 file system. You can't access your EC2 instance by Secure Shell (SSH) using this security group. For access by SSH, you can later edit the default security group and add a rule to allow SSH, or add a new security group that allows SSH. You can use the following settings:

   i. **Type:** SSH

   ii. **Protocol:** TCP

   iii. **Port Range:** 22

   iv. **Source:** Anywhere 0.0.0.0/0

4. Under **Configure storage**, do the following:

   a. Under **File systems**, choose **S3 Files**.

   b. Choose **Add shared file system**.

   c. For **S3 file system**, your file systems appear in the Availability Zone based on the subnet that you selected in your Network settings. Choose the S3 file system that you want to mount. If you don’t have any file systems, choose **Create a new file system** to create a new one.

   d. Enter a local mount path on your EC2 instance where you want to mount the file system (for example, `/mnt/s3files`).

   e. A command will be generated to mount the file system and add it to fstab. You can add this command to the **User data** field under **Advanced details**. Your EC2 instance will then be configured to mount the S3 file system at launch and whenever it's rebooted. You can also run these commands in your EC2 instance after it is launched.

5. Under **Advanced details**, attach an instance profile to your instance. Your IAM role must have permissions to mount the file system and access the S3 bucket. For more information about the required permissions, see IAM roles and policies in the *Amazon S3 User Guide*.

6. Choose **Launch instance**.

   After the instance launches, the required software utilities are installed and the file system is mounted. You can view the file system by navigating to your local mount path.

To mount a file system to an EC2 instance after launch

1. Connect to your EC2 instance through Secure Shell (SSH) or by using EC2 Instance Connect in the EC2 console.
2. To mount your S3 file system, use the mount helper utility `amazon-efs-utils`. Depending on your Linux distribution, use one of the following commands to install the `amazon-efs-utils` package:

   a. If you're using Amazon Linux, run the following command to install efs-utils from Amazon's repositories:

   ```
   sudo yum -y install amazon-efs-utils
   ```

   b. If you are using other supported Linux distributions, run the following command:

   ```
   curl https://amazon-efs-utils.aws.com/efs-utils-installer.sh | sudo sh -s -- --
   install
   ```

   c. For other Linux distributions, see the efs-utils repository on *GitHub*.
3. Create a directory for the file system mount point using the following command:

   ```
   sudo mkdir {path/to/mount}
   ```
4. Mount the S3 file system:

   ```
   FS="{YOUR_FILE_SYSTEM_ID}"
   sudo mount -t s3files $FS:/ {path/to/mount}
   ```
5. Confirm the file system is mounted:

   ```
   df -h {path/to/mount}
   ```

To view objects in your S3 bucket as files

Having completed the preceding procedures, you can now read and write S3 objects as files on your local mount path using standard file system operations. If you have objects in your S3 bucket, you can view them as files by using the following command:

```
ls {path/to/mount}
```

Object-based access

You can copy files to and from Amazon S3 using the S3 API, AWS CLI, AWS SDKs, or standard HTTP tools. If you have the required permissions, you can copy a file to or from Amazon S3 and your instance using one of the following methods.

wget

> **Note**
>
> This method works for public objects only. If the object is not public, you receive an `ERROR 403: Forbidden` message. If you receive this error, you must use either the Amazon S3 console, AWS CLI, AWS API, AWS SDK, or AWS Tools for Windows PowerShell, and you must have the required permissions. For more information, see Identity and access management for Amazon S3 and Downloading an object in the *Amazon S3 User Guide*.

The **wget** utility is an HTTP and FTP client that you can use to download public objects from Amazon S3. It is installed by default in Amazon Linux and most other distributions, and available for download on Windows. To download an Amazon S3 object, use the following command, substituting the URL of the object to download.

```
[ec2-user ~]$ wget https://amzn-s3-demo-bucket.s3.amazonaws.eu/path-to-file
```

PowerShell

You can use the AWS Tools for Windows PowerShell to move objects to and from Amazon S3.

Use the Copy-S3Object cmdlet to copy an Amazon S3 object to your Windows instance as follows.

```
Copy-S3Object `
    -BucketName amzn-s3-demo-bucket `
    -Key path-to-file `
    -LocalFile my_copied_file.ext
```

Alternatively, you can open the Amazon S3 console by using a web browser on the Windows instance.

AWS CLI

You can use the AWS Command Line Interface (AWS CLI) to download restricted items from Amazon S3 and to upload items. For more information, such as how to install and configure the tools, see the AWS Command Line Interface detail page.

The aws s3 cp command is similar to the Unix **cp** command. You can copy files from Amazon S3 to your instance, copy files from your instance to Amazon S3, and copy files from one Amazon S3 location to another.

Use the following command to copy an object from Amazon S3 to your instance:

```
aws s3 cp s3://amzn-s3-demo-bucket/my_folder/my_file.ext my_copied_file.ext
```

Use the following command to copy an object from your instance back into Amazon S3:

```
aws s3 cp my_copied_file.ext s3://amzn-s3-demo-bucket/my_folder/my_file.ext
```

The aws s3 sync command can synchronize an entire Amazon S3 bucket to a local directory location. This can be helpful for downloading a data set and keeping the local copy up-to-date with the remote set. If you have the proper permissions on the Amazon S3 bucket, you can push your local directory back up to the cloud when you are finished by reversing the source and destination locations in the command.

Use the following command to download an entire Amazon S3 bucket to a local directory on your instance:

```
aws s3 sync s3://amzn-s3-demo-source-bucket local_directory
```

Amazon S3 API

You can use an API to access data in Amazon S3. You can use this API to help develop your application and integrate it with other APIs and SDKs. For more information, see Code examples for Amazon S3 using AWS SDKs in the *Amazon Simple Storage Service API Reference*.

Use Amazon EFS with Amazon EC2 Linux instances

> **Note**
>
> Amazon EFS is not supported on Windows instances.

Amazon EFS provides scalable file storage for use with Amazon EC2. You can use an EFS file system as a common data source for workloads and applications running on multiple instances. For more information, see the Amazon Elastic File System product page.

This tutorial shows you how to create and attach an Amazon EFS file system using the Amazon EFS Quick Create wizard during instance launch. For a tutorial on how to create a file system using the Amazon EFS console, see Getting started with Amazon Elastic File System in the *Amazon Elastic File System User Guide*.

> **Note**
>
> When you create an EFS file system using EFS Quick Create, the file system is created with the following service recommended settings:
>
> - Automatic backups enabled.
> - Manage mount targets in the selected VPC.
> - General Purpose performance mode.
> - Bursting throughput mode.
> - Encryption of data at rest enabled using your default key for Amazon EFS (`aws/elasticfilesystem`).
> - Amazon EFS lifecycle management enabled with a 30-day policy.

Tasks

- Test the EFS file system
- Delete the EFS file system

Test the EFS file system

You can connect to your instance and verify that the file system is mounted to the directory that you specified (for example, /mnt/efs).

To verify that the file system is mounted

1. Connect to your instance. For more information, see Connect to your Linux instance using SSH.
2. From the terminal window for the instance, run the **df -T** command to verify that the EFS file system is mounted.

```
$ df -T
Filesystem     Type              1K-blocks    Used          Available Use% Mounted
 on
/dev/xvda1     ext4                8123812 1949800            6073764  25% /
devtmpfs       devtmpfs            4078468      56            4078412   1% /dev
tmpfs          tmpfs               4089312       0            4089312   0% /dev/shm
efs-dns        nfs4       9007199254740992       0   9007199254740992   0% /mnt/efs
```

   Note that the name of the file system, shown in the example output as *efs-dns*, has the following form.

```
file-system-id.efs.aws-region.amazonaws.com:/
```

3. (Optional) Create a file in the file system from the instance, and then verify that you can view the file from another instance.

   a. From the instance, run the following command to create the file.

```
$ sudo touch /mnt/efs/test-file.txt
```

   b. From the other instance, run the following command to view the file.

```
$ ls /mnt/efs
test-file.txt
```

Delete the EFS file system

If you no longer need your file system, you can delete it.

To delete the file system

1. Open the Amazon Elastic File System console at https://eusc-de-east-1.console.amazonaws-eusc.eu/efs/.
2. Select the file system to delete.
3. Choose **Actions**, **Delete file system**.
4. When prompted for confirmation, enter the file system ID and choose **Delete file system**.

Use Amazon FSx with Amazon EC2 instances

The Amazon FSx family of services makes it easy to launch, run, and scale shared storage powered by popular commercial and open-source file systems. You can use the *new launch instance wizard* to automatically attach the following types of Amazon FSx file systems to your Amazon EC2 instances at launch:

- Amazon FSx for NetApp ONTAP provides fully managed shared storage in the AWS Cloud with the popular data access and management capabilities of NetApp ONTAP.
- Amazon FSx for OpenZFS provides fully managed cost-effective shared storage powered by the popular OpenZFS file system.

> **Note**
>
> - This functionality is available in the new launch instance wizard only. For more information, see Launch an EC2 instance using the launch instance wizard in the console
> - Amazon FSx for Windows File Server and Amazon FSx for Lustre file systems can't be mounted at launch. You must mount these file systems manually after launch.

You can choose to mount an existing file system that you created previously, or you can create a new file system to mount to an instance at launch.

Topics

- Security groups and user data script
- Mount an Amazon FSx file system at launch

Security groups and user data script

When you mount an Amazon FSx file system to an instance using the launch instance wizard, you can choose whether to automatically create and attach the security groups needed to enable access to the file system, and whether to automatically include the user data scripts needed to mount the file system and make it available for use.

Topics

- Security groups
- User data script

Security groups

If you choose to automatically create the security groups that are needed to enable access to the file system, the launch instance wizard creates and attaches two security groups - one security group is attached to the instance, and the other is attached to the file system. For more information about the security group requirements, see FSx for ONTAP file system access control with Amazon VPC and FSx for OpenZFS file system access control with Amazon VPC.

We add the tag `Name=instance-sg-`*`1`* to the security group that is created and attached to the instance. The value in the tag is automatically incremented each time the launch instance wizard creates a security group for Amazon FSx file systems.

The security group includes the following output rules, but no inbound rules.

Outbound rules

Protocol type	Port number	Destination
UDP	111	*file system security group*
UDP	20001 - 20003	*file system security group*
UDP	4049	*file system security group*
UDP	2049	*file system security group*
UDP	635	*file system security group*
UDP	4045 - 4046	*file system security group*

Protocol type	Port number	Destination
TCP	4049	*file system security group*
TCP	635	*file system security group*
TCP	2049	*file system security group*
TCP	111	*file system security group*
TCP	4045 - 4046	*file system security group*
TCP	20001 - 20003	*file system security group*
All	All	*file system security group*

The security group that is created and attached to the file system is tagged with `Name=fsx-sg-`*1*. The value in the tag is automatically incremented each time the launch instance wizard creates a security group for Amazon FSx file systems.

The security group includes the following rules.

Inbound rules

Protocol type	Port number	Source
UDP	2049	*instance security group*
UDP	20001 - 20003	*instance security group*
UDP	4049	*instance security group*
UDP	111	*instance security group*
UDP	635	*instance security group*
UDP	4045 - 4046	*instance security group*
TCP	4045 - 4046	*instance security group*
TCP	635	*instance security group*

Protocol type	Port number	Source
TCP	2049	*instance security group*
TCP	4049	*instance security group*
TCP	20001 - 20003	*instance security group*
TCP	111	*instance security group*

Outbound rules

Protocol type	Port number	Destination
All	All	0.0.0.0/0

User data script

If you choose to automatically attach user data scripts, the launch instance wizard adds the following user data to the instance. This script installs the necessary packages, mounts the file system, and updates your instance settings so that the file system will automatically re-mount whenever the instance restarts.

```
#cloud-config
package_update: true
package_upgrade: true
runcmd:
- yum install -y nfs-utils
- apt-get -y install nfs-common
- svm_id_1=svm_id
- file_system_id_1=file_system_id
- vol_path_1=/vol1
- fsx_mount_point_1=/mnt/fsx/fs1
- mkdir -p "${fsx_mount_point_1}"
- if [ -z "$svm_id_1" ]; then printf "\n${file_system_id_1}.fsx.eu-
north-1.amazonaws.com:/${vol_path_1} ${fsx_mount_point_1} nfs4
 nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport,_netdev
 0 0\n" >> /etc/fstab; else printf "\n${svm_id_1}.${file_system_id_1}.fsx.eu-
north-1.amazonaws.com:/${vol_path_1} ${fsx_mount_point_1} nfs4
```

```
 nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport,_netdev 0
 0\n" >> /etc/fstab; fi
- retryCnt=15; waitTime=30; while true; do mount -a -t nfs4 defaults; if [ $? = 0 ] ||
 [ $retryCnt -lt 1 ]; then echo File system mounted successfully; break; fi; echo File
 system not available, retrying to mount.; ((retryCnt--)); sleep $waitTime; done;
```

Mount an Amazon FSx file system at launch

To mount a new or existing Amazon FSx file system at launch

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances** and then choose **Launch instance** to open the launch instance wizard.
3. In the **Application and OS Images** section, select the AMI to use.
4. In the **Instance type** section, select the instance type.
5. In the **Key pair** section, select an existing key pair or create a new one.
6. In the **Network settings** section, do the following:

   a. Choose **Edit**.

   b. If you want to **mount an existing file system**, for **Subnet**, choose the file system's preferred subnet. We recommend that you launch the instance into the same Availability Zone as the file system's preferred subnet to optimize performance.

   If you want to **create a new file system** to mount to an instance, for **Subnet**, choose the subnet into which to launch the instance.

   > **Important**
   >
   > You must select a subnet to enable the Amazon FSx functionality in the new launch instance wizard. If you do not select a subnet, you will not be able to mount an existing file system or create a new one.

7. In the **Storage** section, do the following:

   a. Configure the volumes as needed.

   b. Expand the **File systems** section and select **FSx**.

   c. Choose **Add shared file system**.

d. For **File system**, select the file system to mount.

> **Note**
>
> The list displays all Amazon FSx for NetApp ONTAP and Amazon FSx for OpenZFS file systems in your account in the selected Region.

e. To automatically create and attach the security groups needed to enable access to the file system, select **Automatically create and attach security groups**. If you prefer to create the security groups manually, clear the checkbox. For more information, see Security groups.

f. To automatically attach the user data scripts needed to mount the file system, select **Automatically mount shared file system by attaching required user data script**. If you prefer to provide the user data scripts manually, clear the checkbox. For more information, see User data script.

8. In the **Advanced** section, configure the additional instance settings as needed.
9. Choose **Launch**.

Use Amazon File Cache with Amazon EC2 instances

Amazon File Cache provides a fully managed, high-speed cache on AWS that makes it easier to process file data, regardless of where the data is stored. Amazon File Cache serves as a temporary, high-performance storage location for data that's stored in on-premises file systems, AWS file systems, and Amazon Simple Storage Service (Amazon S3) buckets. You can use this capability to make dispersed datasets available to file-based applications on AWS with a unified view, and at high speeds—sub-millisecond latencies and high throughput. For more information, see the Amazon File Cache User Guide.

Amazon File Cache works with the most popular Linux AMIs, and is compatible with x86-based instance types and Graviton instance types. You can access your cache from your Amazon EC2 instances using the open-source Lustre client. You can mount your cache and then work with the files and directories in your cache using standard Linux commands. Amazon EC2 instances can access your cache from other Availability Zones within the same virtual private cloud (VPC), provided that your network configuration allows access across subnets within the VPC. You can also create a cache in a shared VPC.

To get started, see Getting started with Amazon File Cache in the *Amazon File Cache User Guide*.

Manage your Amazon EC2 resources

A *resource* is an entity that you can work with. Amazon EC2 creates resources as you use the features of the service. For example, Amazon EC2 resources include images, instances, fleets, key pairs, and security groups. All Amazon EC2 resource types include attributes that describe the resources. For example, names, descriptions, resource identifiers, and Amazon Resource Names (ARN).

Amazon EC2 resources are specific to the AWS Region or zone in which they reside. For example, an Amazon Machine Image (AMI) is specific to an AWS Region, but the instance that you launch from an AMI is specific to the zone in which you launch it. You can specify an Amazon EC2 resource in a permissions policy using its ARN.

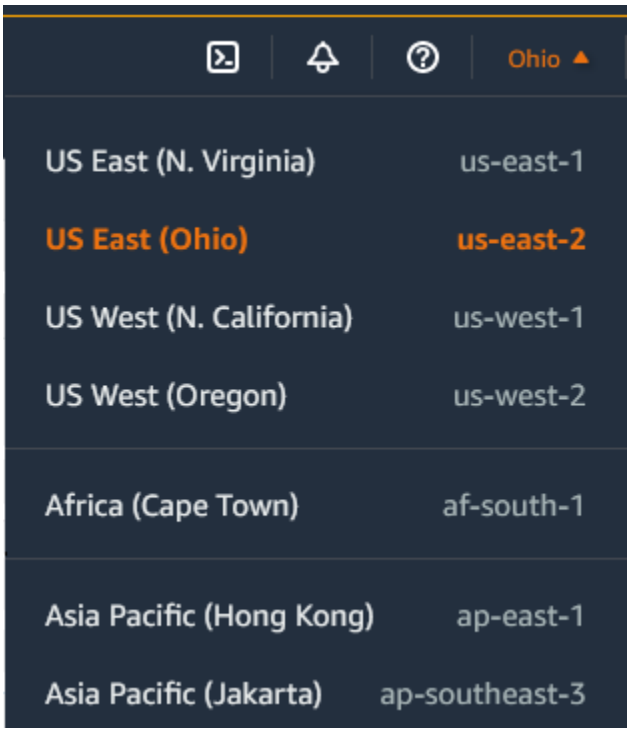
Your AWS account has default quotas for Amazon EC2. These quotas define the maximum number of resources that you can create. For example, there are quotas for the maximum number of vCPUs across your running instances. If launching an instance or starting a stopped instance would cause you to exceed your quota, the operation fails.

You can search for specific resources in your AWS account by Region, using resource IDs or tags. To search for specific resources or resource types across multiple Regions, use Amazon EC2 Global View.

Contents

- Select a Region for your Amazon EC2 resources
- Find your Amazon EC2 resources
- View resources across Regions using AWS Global View
- Tag your Amazon EC2 resources
- Amazon EC2 service quotas

Select a Region for your Amazon EC2 resources



Amazon EC2 resources are specific to the AWS Region or zone in which they reside. When you create an Amazon EC2 resource, you select the Region for the resource.

Considerations

- Some AWS resources might not be available in all Regions. Ensure that you can create all the AWS resources that you need in a Region before you start creating resources in a Region.
- Some Regions are disabled by default. You must enable these Regions before you can use them. For more information , see AWS Regions.

To select a Region for a resource using the console

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. From the navigation bar, choose the **Regions** selector and then choose the Region.

3. The Regions selector includes all resources that are available for use in your AWS account. Choose the underlined text near the bottom of the list to view the Regions that are not enabled for your account.

To select a Region for a resource using the AWS CLI

You can configure the AWS CLI to use a default Region. If you don't specify a Region in the command, the default Region is used. To use a different Region for a specific command, add the following option.

```
--region eusc-de-east-1
```

To select a Region for a resource using the Tools for PowerShell

You can configure the Tools for Windows PowerShell to use a default Region. If you don't specify a Region in a command, the default Region is used. To use a different Region for a specific command, add the following parameter.

```
-Region eusc-de-east-1
```

Find your Amazon EC2 resources

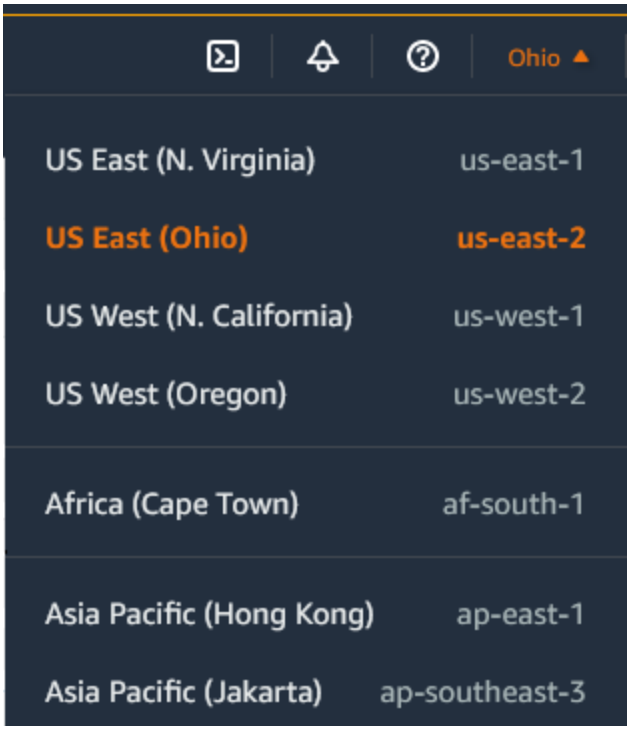
You can get a list of some types of resources using the Amazon EC2 console. You can get a list of each type of resource using its corresponding command or API action. If you have many resources, you can filter the results to include, or exclude, only the resources that match certain criteria.

Contents

- List and filter resources using the console
- List and filter using the command line
- View resources across Regions using AWS Global View

List and filter resources using the console

Contents



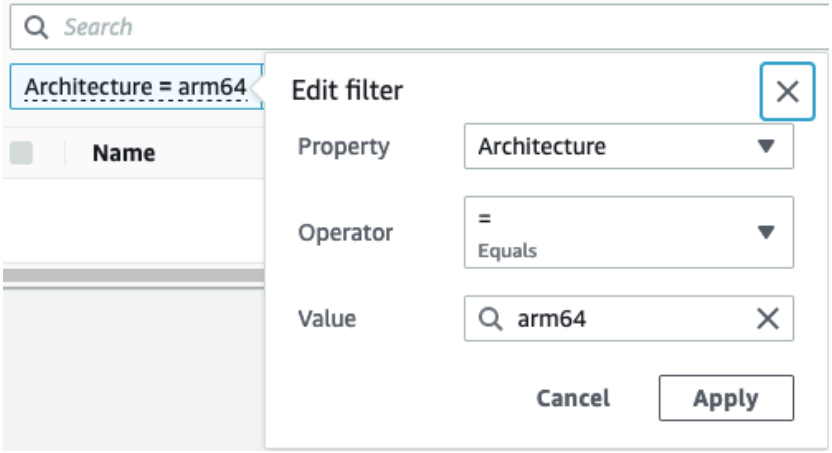
- List resources using the console
- Filter resources using the console
  - Supported filters
- Save filter sets using the console
  - Key features
  - Create a filter set
  - Modify a filter set
  - Delete a filter set

List resources using the console

You can view the most common Amazon EC2 resource types using the console. To view additional resources, use the command line interface or the API actions.

To list EC2 resources using the console

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. Amazon EC2 resources are specific to an AWS Region. From the navigation bar, choose a Region from the **Regions** selector.



3. In the navigation pane, choose the option that corresponds to the resource type. For example, to list all your instances, choose **Instances**.

Filter resources using the console

To filter a list of resources

1. In the navigation pane, select a resource type (for example, **Instances**).
2. Choose the search field.
3. Select the filter from the list.

4. Select an operator, for example, **= (Equals)**. Some attributes have more available operators to select. Note that not all screens support selecting an operator.
5. Select a filter value.
6. To edit a selected filter, choose the filter token (blue box), make the required edits, and then choose **Apply**. Note that not all screens support editing the selected filter.

7. When you are finished, remove the filter.

Supported filters

The Amazon EC2 console supports two types of filtering.

- *API filtering* happens on the server side. The filtering is applied on the API call, which reduces the number of resources returned by the server. It allows for quick filtering across large sets of resources, and it can reduce data transfer time and cost between the server and the browser. API filtering supports **=** (equals) and **:** (contains) operators, and is always case sensitive.
- *Client filtering* happens on the client side. It enables you to filter down on data that is already available in the browser (in other words, data that has already been returned by the API). Client filtering works well in conjunction with an API filter to filter down to smaller data sets in the browser. In addition to **=** (equals) and **:** (contains) operators, client filtering can also support range operators, such as **>=** (greater than or equal), and negation (inverse) operators, such as **!=** (does not equal).

The Amazon EC2 console supports the following types of searches:

Search by keyword

Searching by keyword is a free text search that lets you search for a value across all of your resources' attributes or tags, without specifying an attribute or tag key to search.

> **Note**
>
> All keyword searches use *client filtering*.

To search by keyword, enter or paste what you're looking for in the search field, and then choose **Enter**. For example, searching for 123 matches all instances that have *123* in any of their attributes, such as an IP address, instance ID, VPC ID, or AMI ID, or in any of their tags, such as the Name. If your free text search returns unexpected matches, apply additional filters.

Search by attribute

Searching by an attribute lets you search a specific attribute across all of your resources.

> **Note**
>
> Attribute searches use either *API filtering* or *client filtering*, depending on the selected attribute. When performing an attribute search, the attributes are grouped accordingly.

For example, you can search the **Instance state** attribute for all of your instances to return only instances that are in the `stopped` state. To do this:

1. In the search field on the **Instances** screen, start entering `Instance state`. As you enter the characters, the two types of filters appear for **Instance state**: **API filters** and **Client filters**.
2. To search on the server side, choose **Instance state** under **API filters**. To search on the client side, choose **Instance state (client)** under **Client filters**.

   A list of possible operators for the selected attribute appears.
3. Choose the **=** (Equals) operator.

   A list of possible values for the selected attribute and operator appears.
4. Choose **stopped** from the list.

Search by tag

Searching by a tag lets you filter the resources in the currently displayed table by a tag key or a tag value.

Tag searches use either *API filtering* or *client filtering*, depending on the settings in the Preferences window.

To ensure API filtering for tags

1. Open the **Preferences** window.
2. Clear the **Use regular expression matching** checkbox. If this checkbox is selected, client filtering is performed.
3. Select the **Use case sensitive matching** checkbox. If this checkbox is cleared, client filtering is performed.
4. Choose **Confirm**.

When searching by tag, you can use the following values:

- **(empty)** – Find all resources with the specified tag key, but there must be no tag value.
- **All values** – Find all resources with the specified tag key and any tag value.
- **Not tagged** – Find all resources that do not have the specified tag key.
- The displayed value – Find all resources with the specified tag key and the specified tag value.

You can use the following techniques to enhance or refine your searches:

Inverse search

Inverse searches let you search for resources that do **not** match a specified value. In the **Instances** and **AMIs** screens, inverse searches are performed by selecting the **!=** (Does not equal) or **!:** (Does not contain) operator and then selecting a value. In other screens, inverse searches are performed by prefixing the search keyword with the exclamation mark (!) character.

> **Note**
>
> Inverse search is supported with keyword searches and attribute searches on *client* filters only. It is not supported with attribute searches on API filters.

For example, you can search the **Instance state** attribute for all of your instances to exclude all instances that are in the `terminated` state. To do this:

1. In the search field on the **Instances** screen, start entering `Instance state`. As you enter the characters, the two types of filters appear for **Instance state**: **API filters** and **Client filters**.
2. Under **Client filters**, choose **Instance state (client)**. Inverse search is only supported on *client* filters.

   A list of possible operators for the selected attribute appears.
3. Choose **!=** (Does not equal), and then choose **terminated**.

To filter instances based on an instance state attribute, you can also use the search icons (

) in the **Instance state** column. The search icon with a plus sign (**+**) displays all the instances that *match* that attribute. The search icon with a minus sign (**-**) *excludes* all instances that match that attribute.

Here is another example of using the inverse search: To list all instances that are **not** assigned the security group named `launch-wizard-1`, under **Client filters**, search by the **Security group name** attribute, choose **!=**, and in the search bar, enter `launch-wizard-1`.

Partial search

With partial searches, you can search for partial string values. To perform a partial search, enter only a part of the keyword that you want to search for. On the **Instances** and **AMIs** screens, partial searches can only be performed with the **:** (Contains) operator. On other screens, you can select the client filter attribute and immediately enter only a part of the keyword that you want to search for. For example, on the **Instance type** screen, to search for all `t2.micro`, `t2.small`, and `t2.medium` instances, search by the **Instance Type** attribute, and for the keyword, enter `t2`.

Regular expression search

To use regular expression searches, you must select the **Use regular expression matching** checkbox in the **Preferences** window.

Regular expressions are useful when you need to match the values in a field with a specific pattern. For example, to search for a value that starts with `s`, search for `^s`. To search for a value that ends with `xyz`, search for `xyz$`. Or to search for a value that starts with a number that is followed by one or more characters, search for `[0-9]+.*`.

> **Note**
>
> Regular expression search is supported with keyword searches and attribute searches on client filters only. It is not supported with attribute searches on API filters.

Case-sensitive search

To use case-sensitive searches, you must select the **Use case sensitive matching** checkbox in the **Preferences** window. The case-sensitive preference only applies to client and tag filters.

> **Note**
>
> API filters are always case-sensitive.

Wildcard search

Use the * wildcard to match zero or more characters. Use the ? wildcard to match zero or one character. For example, if you have a data set with the values `prod`, `prods`, and `production`, a search of `prod*` matches all values, whereas `prod?` matches only `prod` and `prods`. To use the literal values, escape them with a backslash (\). For example, "`prod\*`" would match `prod*`.

> **Note**
>
> Wildcard search is supported with attribute and tag searches on API filters only. It is not supported with keyword searches, and with attribute and tag searches on client filters.

Combining searches

In general, multiple filters with the same attribute are automatically joined with OR. For example, searching for `Instance State : Running` and `Instance State : Stopped` returns all instances that are either running OR stopped. To join search with AND, search across different attributes. For example, searching for `Instance State : Running` and `Instance Type : c4.large` returns only instances that are of type `c4.large` AND that are in the running state.

Save filter sets using the console

A *saved filter set* is a customized group of filters that you can create and reuse to efficiently view your Amazon EC2 resources. This feature helps streamline your workflow, enabling quick access to specific resource views.

Saved filter sets are only supported in the Amazon EC2 console and are currently only available for the **Volumes** page.

Key features

- **Customization:** Create filter sets tailored to your needs. For example, you can create a filter set to display only your gp3 volumes that were created after a specified date.
- **Default filter:** Set a default filter set for a page, and the default filters are automatically applied when you navigate to the page. If no default is set, no filters are applied.
- **Easy application:** Select a saved filter set to apply it instantly. Amazon EC2 then displays the relevant resources, with the active filters indicated by blue tokens.
- **Flexibility:** Create, modify, and delete filter sets as needed.

Create a filter set

To create a new filter set

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Volumes**.

   > **Note**
   >
   > Saved filter sets are currently only available for **Volumes**.

3. In the search field, select filters for your filter set.
4. Choose the arrow next to the **Clear filters** button, and choose **Save new filter set**.
5. In the **Save filter set** window, do the following:

   a. For **Filter set name**, enter a name for the filter set.

   b. (Optional) For **Filter set description**, enter a description for the filter set.

   c. (Optional) To set the filter set as the default filter, select the **Set as default** checkbox.

> **Note**
>
> The default filter is automatically applied every time you open the console page.

d. Choose **Save**.

Modify a filter set

To modify a filter set

1. From the **Saved filter sets** list, select the filter to modify.
2. To add a filter, in the search field, select a filter to add to your filter set. To delete a filter in the set, choose the **X** on the filter token.
3. Choose the arrow next to the **Clear filters** button, and choose **Modify filter set**.
4. In the **Modify filter set** window, do the following:

   a. (Optional) To set the filter set as the default filter, select the **Set as default** checkbox.

   > **Note**
   >
   > The default filter is automatically applied every time you open the console page.

   b. Choose **Modify**.

Delete a filter set

To delete a filter set

1. From the **Saved filter sets** list, select the filter to delete.
2. Choose the arrow next to the **Clear filters** button, and choose **Delete filter set**.
3. In the **Delete filter set** window, review the filter to confirm this is the filter you want to delete, and then choose **Delete**.

List and filter using the command line

Each resource type has a corresponding API actions that you use to describe, list, or get resources of that type. The resulting lists of resources can be long, so it can be faster and more useful to filter the results to include only the resources that match specific criteria.

Filtering considerations

- You can specify up to 50 filters and up to 200 total filter values in a single request.
- Filter strings can be up to 255 characters in length.
- You can use wildcards with the filter values. An asterisk (*) matches zero or more characters, and a question mark (?) matches zero or one character.
- Filter values are case sensitive.
- Your search can include the literal values of the wildcard characters; you just need to escape them with a backslash before the character. For example, a value of `\*amazon\?\\` searches for the literal string `*amazon?\`.
- You can't specify a filter value of null. Instead, use client-side filtering. For example, the following command uses the **--query** option and returns the IDs of the instances that were launched without a key pair.

```
aws ec2 describe-instances \
    --query 'Reservations[*].Instances[?!not_null(KeyName)].InstanceId' \
    --output text
```

AWS CLI

Example: Specify a single filter

You can list your Amazon EC2 instances using describe-instances. Without filters, the response contains information for all of your resources. You can use the following option to include only the running instances in the output.

```
--filters Name=instance-state-name,Values=running
```

To list only the instance IDs for your running instances, add the `--query` option as follows.

```
--query "Reservations[*].Instances[*].InstanceId"
```

Example: Specify multiple filters or filter values

If you specify multiple filters or multiple filter values, the resource must match all filters to be included in the output.

You can use the following option to list all instances whose type is either `m5.large` or `m5d.large`.

```
--filters Name=instance-type,Values=m5.large,m5d.large
```

You can use the following option to list all stopped instances whose type is `t2.micro`.

```
--filters Name=instance-state-name,Values=stopped Name=instance-type,Values=t2.micro
```

Example: Use wildcards in a filter value

You can use the following option with describe-snapshots to return only the snapshots whose description is "database".

```
--filters Name=description,Values=database
```

The * wildcard matches zero or more characters. You can use the following option to return only the snapshots whose description includes the word database.

```
--filters Name=description,Values=*database*
```

The ? wildcard matches exactly 1 character. You can use the following option to return only the snapshots whose description is "database" or "database" followed by one character.

```
--filters Name=description,Values=database?
```

You can use the following option to return only the snapshots whose description is "database" followed by up to four characters. This excludes descriptions with "database" followed by five or more characters.

```
--filters Name=description,Values=database????
```

Example: Filter based on date

With the AWS CLI, you can use JMESPath to filter results using expressions. For example, the following describe-snapshots command displays the IDs of all snapshots created by the specified AWS account before the specified date. If you do not specify the owner, the results include all public snapshots.

```
aws ec2 describe-snapshots \
    --filters Name=owner-id,Values=123456789012 \
    --query "Snapshots[?(StartTime<='2024-03-31')].[SnapshotId]" \
    --output text
```

The following example displays the IDs of all snapshots created in the specified date range.

```
aws ec2 describe-snapshots \
    --filters Name=owner-id,Values=123456789012 \
    --query "Snapshots[?(StartTime>='2024-01-01') && (StartTime<='2024-12-31')].
[SnapshotId]" \
    --output text
```

Example: Filter based on tags

For examples of how to filter a list of resources according to their tags, see Filter Amazon EC2 resources by tag.

PowerShell

Example: Specify a single filter

You can list your Amazon EC2 instances using Get-EC2Instance. Without filters, the response contains information for all of your resources. You can use the following parameter to include only the running instances in the output.

```
-Filter @{Name="instance-state-name"; Values="running"}
```

The following example lists only the instance IDs for your running instances.

```
(Get-EC2Instance -Filter @{Name="instance-state-name"; Values="stopped"}).Instances
 | Select InstanceId
```

Example: Specify multiple filters or filter values

If you specify multiple filters or multiple filter values, the resource must match all filters to be included in the results.

You can use the following option to list all instances whose type is either `m5.large` or `m5d.large`.

```
-Filter @{Name="instance-type"; Values="m5.large", "m5d.large"}
```

You can use the following option to list all stopped instances whose type is `t2.micro`.

```
-Filter @{Name="instance-state-name"; Values="stopped"}, @{Name="instance-type";
 Values="t2.micro"}
```

View resources across Regions using AWS Global View

AWS Global View enables you to view and search for resources in a single AWS Region, or across multiple Regions simultaneously in a single console. For more information, see View resources across Regions using AWS Global View.

View resources across Regions using AWS Global View

AWS Global View enables you to view some of your resources across a single AWS Region, or across multiple Regions in a single console. AWS Global View also provides *global search* functionality that lets you search for specific resources or specific resource types across multiple Regions simultaneously.

AWS Global View does not let you modify resources in any way.

Supported resources

Using AWS Global View, you can view a global summary of the following resources across all of the Regions for which your AWS account is enabled.

- Auto Scaling groups
- Availability Zones
- Capacity Reservations and Capacity Blocks
- DB clusters

- DB instances
- DHCP option set
- Amazon Elastic Container Service (Amazon ECS) clusters
- ECS services
- ECS tasks
- Egress-only internet gateways
- Elastic IPs
- Endpoint services
- Instances
- Internet gateways
- Managed prefix lists
- NAT gateways
- Network ACLs
- Network interfaces
- Outposts
- Route tables
- S3 buckets
- Security groups
- Subnets
- Volumes
- VPCs
- VPC endpoints
- VPC peering connections

Required permissions

A user must have the following permissions to use AWS Global View.

JSON

```
{
  "Version":"2012-10-17",
```

```
  "Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "autoscaling:DescribeAutoScalingGroups",
      "ec2:DescribeRegions",
      "ec2:DescribeCapacityReservations",
      "ec2:DescribeDhcpOptions",
      "ec2:DescribeEgressOnlyInternetGateways",
      "ec2:DescribeAddresses",
      "ec2:DescribeVpcEndpointServices",
      "ec2:DescribeInstances",
      "ec2:DescribeInternetGateways",
      "ec2:DescribePrefixLists",
      "ec2:DescribeNatGateways",
      "ec2:DescribeNetworkAcls",
      "ec2:DescribeNetworkInterfaces",
      "ec2:DescribeRouteTables",
      "ec2:DescribeSecurityGroups",

  ],
  "Resource": "*"
  }]
}
```

To use AWS Global View

Sign in to the AWS Global View console.

> **Important**
>
> You cannot use a private window in Firefox to access AWS Global View.

The console consists of the following:

- **Region explorer** – This page includes the following sections:
  - **Summary** – Provides a high-level overview of your resources across all Regions.

    Expand **Show all resource summary** indicates the number of Regions for which your AWS account is enabled. The remaining fields indicate the number of resources that you currently have in those Regions. Choose any of the links to view the resources of that type across all Regions. For example, if the link below the **Instances** label is **29 in 10 Regions**, it indicates that you currently have 29 instances across 10 Regions. Choose the link to view a list of all 29 instances.
  - **Region explorer** – Lists all of the AWS Regions (including those for which your account is not enabled) and provides totals for each resource type for each Region.

    Choose a Region name to view all resources of all types for that specific Region. For example, choose **Africa (Cape Town) af-south-1** to view all VPCs, subnets, instances, security groups, volumes, and Auto Scaling groups in that Region. Alternatively, select a Region and choose **View resources for selected Region**.

    Choose the value for a specific resource type in a specific Region to view only resources of that type in that Region. For example, choose the value for Instances for **Africa (Cape Town) af-south-1** to view only the instances in that Region.
- **Global search** – This page enables you to search for specific resources or specific resource types across a single Region or across multiple Regions. It also enables you to view details for a specific resource.

  To search for resources, enter the search criteria in the field preceding the grid. You can search by Region, by resource type, and by the tags assigned to resources.

  To view the details for a specific resource, select it in the grid. You can also choose the resource ID of a resource to open it in its respective console. For example, choose an instance ID to open the instance in the Amazon EC2 console, or choose a subnet ID to open the subnet in the Amazon VPC console.

- **Regions and Zones** – This page allows you to view and manage all available Regions, Availability Zones, Local Zones, and Wavelength Zones. You can switch between **List view** and **Map view** using the **List view/Map view** toggle. Your view preference persists across sessions.
  - **Map view** – Displays all Regions and Zones on an interactive world map, colored by status. To see details for a location, point to it or choose it. Choose a location to take action – you can enable a Region, enable a Zone, or open its detail page. You can also filter the map to show only specific statuses. The map and the detail list stay synchronized – selecting a location on one highlights it on the other.
  - **List view** – Displays Regions and Zones in a table. From the **Regions** tab, you can view all AWS Regions. The **Status** column shows the Regions that are enabled for your AWS account.

  From this page, you can select a Region to:
  - View details of the Region such as the Region code, Geography, and number of each type of Zone.

    You can also view the list of Availability Zones, Local Zones, and Wavelength Zones and the list of your resources in the Region.
  - Enable or disable the Region.

  From each zone tab, you can view the list of that zone type. From the **Local Zones** tab, you can opt-in to a Local Zone.

> **Tip**
>
> If you only use specific Regions or resource types, you can customize AWS Global View to display only those Regions and resource types. To customize the displayed Regions and resource types, in the navigation panel, choose **Settings**, and then on the **Resources** and **Regions** tabs, select the Regions and resource types that you do not want to be displayed in AWS Global View.

Tag your Amazon EC2 resources

To help you manage your instances, images, and other Amazon EC2 resources, you can assign your own metadata to each resource in the form of *tags*. Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This is useful when

you have many resources of the same type—you can quickly identify a specific resource based on the tags that you've assigned to it. This topic describes tags and shows you how to create them.

Warning

Tag keys and their values are returned by many different API calls. Denying access to `DescribeTags` doesn't automatically deny access to tags returned by other APIs. As a best practice, we recommend that you do not include sensitive data in your tags.

Contents

- Add and remove tags for Amazon EC2 resources
- Filter Amazon EC2 resources by tag
- View tags for your EC2 instances using instance metadata

Tag basics

A tag is a label that you assign to an AWS resource. Each tag consists of a *key* and an optional *value*, both of which you define.

Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. For example, you could define a set of tags for your account's Amazon EC2 instances that helps you track each instance's owner and stack level.

The following diagram illustrates how tagging works. In this example, you've assigned two tags to each of your instances—one tag with the key `Owner` and another with the key `Stack`. Each tag also has an associated value.

We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add. For more information about how to implement an effective resource tagging strategy, see the Tagging Best Practices AWS Whitepaper.

Tags don't have any semantic meaning to Amazon EC2 and are interpreted strictly as a string of characters. Also, tags are not automatically assigned to your resources. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set the value of a tag to an empty string, but you can't set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value. If you delete a resource, any tags for the resource are also deleted.

For AMIs, you can share tags with other AWS accounts by using the `ec2:SharedTag/` prefix. For more information, see Sharing tags.

> **Note**
>
> After you delete a resource, its tags might remain visible in the console, API, and CLI output for a short period. These tags will be gradually disassociated from the resource and be permanently deleted.

Tag your resources

When you use the Amazon EC2 console, you can apply tags to resources by using the **Tags** tab on the relevant resource screen, or you can use the **Tags Editor** in the AWS Resource Groups console. Some resource screens enable you to specify tags for a resource when you create the resource; for example, a tag with a key of `Name` and a value that you specify. In most cases, the console applies the tags immediately after the resource is created (rather than during resource creation). The console might organize resources according to the `Name` tag, but this tag doesn't have any semantic meaning to the Amazon EC2 service.

If you're using the Amazon EC2 API, the AWS CLI, or an AWS SDK, you can use the `CreateTags` EC2 API action to apply tags to existing resources. Additionally, some resource-creating actions enable you to specify tags for a resource when the resource is created. If tags cannot be applied during resource creation, we roll back the resource creation process. This ensures that resources are either created with tags or not created at all, and that no resources are left untagged at any time. By tagging resources at the time of creation, you can eliminate the need to run custom tagging scripts after resource creation. For more information about enabling users to tag resources on creation, see Grant permission to tag Amazon EC2 resources during creation.

You can apply tag-based resource-level permissions in your IAM policies to the Amazon EC2 API actions that support tagging on creation to implement granular control over the users and groups that can tag resources on creation. Your resources are properly secured from creation—tags are applied immediately to your resources, therefore any tag-based resource-level permissions controlling the use of resources are immediately effective. Your resources can be tracked and reported on more accurately. You can enforce the use of tagging on new resources, and control which tag keys and values are set on your resources.

You can also apply resource-level permissions to the `CreateTags` and `DeleteTags` Amazon EC2 API actions in your IAM policies to control which tag keys and values are set on your existing resources. For more information, see Example: Tag resources.

For more information about tagging your resources for billing, see Using cost allocation tags in the *AWS Billing User Guide*.

Tag restrictions

The following basic restrictions apply to tags:

- Maximum number of tags per resource – 50

- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum key length – 128 Unicode characters in UTF-8
- Maximum value length – 256 Unicode characters in UTF-8
- Allowed characters
  - Although EC2 allows for any character in its tags, other AWS services are more restrictive. The allowed characters across all AWS services are: letters (`a-z`, `A-Z`), numbers (`0-9`), and spaces representable in UTF-8, and the following characters: `+ - = . _ : / @`.
  - If you enable instance tags in instance metadata, instance tag *keys* can only use letters (`a-z`, `A-Z`), numbers (`0-9`), and the following characters: `+ - = . , _ : @`. Instance tag *keys* can't contain spaces or `/`, and can't comprise only `.` (one period), `..` (two periods), or `_index`. For more information, see View tags for your EC2 instances using instance metadata.
- Tag keys and values are case-sensitive.
- The `aws:` prefix is reserved for AWS use. If a tag has a tag key with this prefix, then you can't edit or delete the tag's key or value. Tags with the `aws:` prefix do not count against your tags per resource limit.

You can't terminate, stop, or delete a resource based solely on its tags; you must specify the resource identifier. For example, to delete snapshots that you tagged with a tag key called `DeleteMe`, you must use the `DeleteSnapshots` action with the resource identifiers of the snapshots, such as `snap-1234567890abcdef0`.

When you tag public or shared resources, the tags you assign are available only to your AWS account; no other AWS account will have access to those tags. For tag-based access control to shared resources, each AWS account must assign its own set of tags to control access to the resource. For an exception to this rule, see Sharing tags.

Sharing tags

By default, user-defined tags are private to the AWS account that creates them. However, for image resources, you can use the `ec2:SharedTag/` prefix to create tags that are visible to all AWS accounts with which you share the image.

The following rules apply to shared tags:

- Amazon EC2 supports shared tags only for image resources. You cannot use the `ec2:SharedTag/` prefix on other EC2 resource types.

- Only the resource owner can create, modify, or delete tags with the `ec2:SharedTag/` prefix. Accounts with which you share the image can view these tags but cannot change them.
- Shared tags count against the resource owner's tags-per-resource quota (50 tags per resource). They do not count against the quota of accounts with which you share the image.
- When you copy an image that has shared tags, Amazon EC2 copies the shared tags to the new image.
- Shared tags can affect access management. Before you share tags, review Tags and access management.

Tags and access management

If you're using AWS Identity and Access Management (IAM), you can control which users in your AWS account have permission to create, edit, or delete tags. For more information, see Grant permission to tag Amazon EC2 resources during creation.

You can also use resource tags to implement attribute-based control (ABAC). You can create IAM policies that allow operations based on the tags for the resource. For more information, see Control access using attribute-based access.

When you use shared tags (tags with the `ec2:SharedTag/` prefix), be aware of the access-management implications. Unlike other user-defined tags, shared tags are visible to every AWS account that you share the image with. We recommend that you use shared tags only for values that you intend all accounts with access to see. If those accounts have attribute-based access control (ABAC) policies that evaluate tags, those policies also apply to the shared image. Only the resource owner can create, modify, or delete shared tags. As a result, accounts that you share the image with can't change the tag values that their policies depend on. When you use a shared image, the image owner sets its `ec2:SharedTag/` tags and you can't change them, so account for these tags in any ABAC policies that you use to control access to the image. For more information about shared tags, see Sharing tags.

Tag your resources for billing

You can use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. For more information about setting up a cost allocation report with tags, see Monthly cost allocation report in the *AWS Billing User Guide*. To see the cost of your combined resources, you can organize your billing information based on

resources that have the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see Using cost allocation tags in the *AWS Billing User Guide*.

> **Note**
>
> If you've just enabled reporting, data for the current month is available for viewing after 24 hours.

Cost allocation tags can indicate which resources are contributing to costs, but deleting or deactivating resources doesn't always reduce costs. For example, snapshot data that is referenced by another snapshot is preserved, even if the snapshot that contains the original data is deleted. For more information, see Amazon Elastic Block Store volumes and snapshots in the *AWS Billing User Guide*.

> **Note**
>
> Elastic IP addresses that are tagged do not appear on your cost allocation report.

Grant permission to tag Amazon EC2 resources during creation

Some resource-creating Amazon EC2 API actions enable you to specify tags when you create the resource. You can use resource tags to implement attribute-based control (ABAC). For more information, see Tag your resources and Control access using attribute-based access.

To enable users to tag resources on creation, they must have permissions to use the action that creates the resource, such as `ec2:RunInstances` or `ec2:CreateVolume`. If tags are specified in the resource-creating action, Amazon performs additional authorization on the `ec2:CreateTags` action to verify if users have permissions to create tags. Therefore, users must also have explicit permissions to use the `ec2:CreateTags` action.

In the IAM policy definition for the `ec2:CreateTags` action, use the `Condition` element with the `ec2:CreateAction` condition key to give tagging permissions to the action that creates the resource.

The following example demonstrates a policy that allows users to launch instances and apply any tags to instances and volumes during launch. Users are not permitted to tag any existing resources (they cannot call the `ec2:CreateTags` action directly).

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateTags"
      ],
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:*/*",
      "Condition": {
         "StringEquals": {
             "ec2:CreateAction" : "RunInstances"
          }
       }
    }
  ]
}
```

Similarly, the following policy allows users to create volumes and apply any tags to the volumes during volume creation. Users are not permitted to tag any existing resources (they cannot call the `ec2:CreateTags` action directly).

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateVolume"
      ],
      "Resource": "*"
    },
    {
```

```
      "Effect": "Allow",
      "Action": [
         "ec2:CreateTags"
      ],
      "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:*/*",
      "Condition": {
         "StringEquals": {
             "ec2:CreateAction" : "CreateVolume"
          }
       }
    }
  ]
}
```

The `ec2:CreateTags` action is only evaluated if tags are applied during the resource-creating action. Therefore, a user that has permissions to create a resource (assuming there are no tagging conditions) does not require permissions to use the `ec2:CreateTags` action if no tags are specified in the request. However, if the user attempts to create a resource with tags, the request fails if the user does not have permissions to use the `ec2:CreateTags` action.

The `ec2:CreateTags` action is also evaluated if tags are provided in a launch template. For an example policy, see Tags in a launch template.

Control access to specific tags

You can use additional conditions in the `Condition` element of your IAM policies to control the tag keys and values that can be applied to resources.

The following condition keys can be used with the examples in the preceding section:

- `aws:RequestTag`: To indicate that a particular tag key or tag key and value must be present in a request. Other tags can also be specified in the request.
  - Use with the `StringEquals` condition operator to enforce a specific tag key and value combination, for example, to enforce the tag `cost-center=cc123`:

    ```
    "StringEquals": { "aws:RequestTag/cost-center": "cc123" }
    ```

  - Use with the `StringLike` condition operator to enforce a specific tag key in the request; for example, to enforce the tag key `purpose`:

    ```
    "StringLike": { "aws:RequestTag/purpose": "*" }
    ```

- `aws:TagKeys`: To enforce the tag keys that are used in the request.
  - Use with the `ForAllValues` modifier to enforce specific tag keys if they are provided in the request (if tags are specified in the request, only specific tag keys are allowed; no other tags are allowed). For example, the tag keys `environment` or `cost-center` are allowed:

    ```
    "ForAllValues:StringEquals": { "aws:TagKeys": ["environment","cost-center"] }
    ```

  - Use with the `ForAnyValue` modifier to enforce the presence of at least one of the specified tag keys in the request. For example, at least one of the tag keys `environment` or `webserver` must be present in the request:

    ```
    "ForAnyValue:StringEquals": { "aws:TagKeys": ["environment","webserver"] }
    ```

These condition keys can be applied to resource-creating actions that support tagging, as well as the `ec2:CreateTags` and `ec2:DeleteTags` actions. To learn whether an Amazon EC2 API action supports tagging, see Actions, resources, and condition keys for Amazon EC2.

To force users to specify tags when they create a resource, you must use the `aws:RequestTag` condition key or the `aws:TagKeys` condition key with the `ForAnyValue` modifier on the resource-creating action. The `ec2:CreateTags` action is not evaluated if a user does not specify tags for the resource-creating action.

For conditions, the condition key is not case-sensitive and the condition value is case-sensitive. Therefore, to enforce the case-sensitivity of a tag key, use the `aws:TagKeys` condition key, where the tag key is specified as a value in the condition.

For example IAM policies, see Example policies to control access the Amazon EC2 API. For more information, see Conditions with multiple context keys or values in the *IAM User Guide*.

Add and remove tags for Amazon EC2 resources

When you create an Amazon EC2 resource, such as an Amazon EC2 instance, you can specify the tags to add to the resource. You can also use the Amazon EC2 console to display the tags for a specific Amazon EC2 resource. You can also add or remove tags from an existing Amazon EC2 resource.

You can use the **Tag Editor** in the AWS Resource Groups console to view, add, or remove tags across of all of your AWS resources across all Regions. You can apply or remove tags from multiple types of resources at the same time. For more information, see the Tagging AWS Resources User Guide.

Tasks

- Add tags using the console
- Add tags using the AWS CLI
- Add tags using PowerShell
- Add tags using CloudFormation

Add tags using the console

You can add tags to an existing resource directly from the page for a resource.

To add tags to an existing resource

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. From the navigation bar, select the Region where the resource is located.
3. In the navigation pane, select a resource type (for example, **Instances**).
4. Select the resource from the list.
5. From the **Tags** tab, choose **Manage tags**.
6. Choose **Add new tag** and enter a key and a value for the tag.
7. Choose **Save**.

Add tags using the AWS CLI

You can add tags when you create a resource or to an existing resource.

To add a tag on resource creation

Use the `-tag-specifications` option to tag a resource on creation. A tag specification requires the type of resource to be tagged, the tag key, and the tag value. The following example creates a tag and adds it to a tag specification.

```
--tag-specifications 'ResourceType=instance,Tags=[{Key=stack,Value=production}]'
```

To add a tag to an existing resource

The following examples demonstrate how to add tags to existing resources using the create-tags command.

Example: Add a tag to a resource

The following command adds the tag **Stack=production** to the specified image, or overwrites an existing tag for the AMI where the tag key is stack. If the command succeeds, no output is returned.

```
aws ec2 create-tags \
    --resources ami-0abcdef1234567890 \
    --tags Key=stack,Value=production
```

Example: Add tags to multiple resources

This example adds (or overwrites) two tags for an AMI and an instance. One of the tags contains just a key (webserver), with no value (we set the value to an empty string). The other tag consists of a key (stack) and value (**Production**). If the command succeeds, no output is returned.

```
aws ec2 create-tags \
    --resources ami-0abcdef1234567890 i-1234567890abcdef0 \
    --tags Key=webserver,Value=  Key=stack,Value=Production
```

Example: Add tags with special characters

This example adds the tag [Group]=test to an instance. The square brackets ([and]) are special characters, which must be escaped.

If you are using Linux or OS X, to escape the special characters, enclose the element with the special character with double quotes ("), and then enclose the entire key and value structure with single quotes (').

```
aws ec2 create-tags \
    --resources i-1234567890abcdef0 \
    --tags 'Key="[Group]",Value=test'
```

If you are using Windows, to escape the special characters, enclose the element that has special characters with double quotes ("), and then precede each double quote character with a backslash (****) as follows:

```
aws ec2 create-tags ^
    --resources i-1234567890abcdef0 ^
    --tags Key=\"[Group]\",Value=test
```

If you are using Windows PowerShell, to escape the special characters, enclose the value that has special characters with double quotes (**"**), precede each double quote character with a backslash (****), and then enclose the entire key and value structure with single quotes (**'**) as follows:

```
aws ec2 create-tags `
    --resources i-1234567890abcdef0 `
    --tags 'Key=\"[Group]\",Value=test'
```

Add tags using PowerShell

You can add tags when you create a resource or to an existing resource.

To add a tag on resource creation

Use the `-TagSpecification` parameter to tag a resource on creation. A tag specification requires the type of resource to be tagged, the tag key, and the tag value. The following example creates a tag and adds it to a tag specification.

```
$tag = @{Key="stack"; Value="production"}
$tagspec = new-object Amazon.EC2.Model.TagSpecification
$tagspec.ResourceType = "instance"
$tagspec.Tags.Add($tag)
```

The following example specifies this tag in the `-TagSpecification` parameter.

```
-TagSpecification $tagspec
```

To add a tag to an existing resource

Use the New-EC2Tag cmdlet. You must specify the resource, the tag key, and the tag value.

```
New-EC2Tag `
    -Resource i-1234567890abcdef0 `
    -Tag @{Key="purpose"; Value="production"}
```

Add tags using CloudFormation

With Amazon EC2 resource types, you specify tags using either a `Tags` or `TagSpecifications` property.

The following examples add the tag **`Stack=Production`** to AWS::EC2::Instance using its `Tags` property.

Example: Tags in YAML

```
Tags:
  - Key: "Stack"
    Value: "Production"
```

Example: Tags in JSON

```
"Tags": [
    {
        "Key": "Stack",
        "Value": "Production"
    }
]
```

The following examples add the tag **`Stack=Production`** to AWS::EC2::LaunchTemplate LaunchTemplateData using its `TagSpecifications` property.

Example: TagSpecifications in YAML

```
TagSpecifications:
  - ResourceType: "instance"
    Tags:
    - Key: "Stack"
      Value: "Production"
```

Example: TagSpecifications in JSON

```
"TagSpecifications": [
    {
        "ResourceType": "instance",
        "Tags": [
            {
                "Key": "Stack",
```

```
                "Value": "Production"
            }
        ]
    }
]
```

Filter Amazon EC2 resources by tag

After you add tags, you can filter your Amazon EC2 resources based tag keys and tag values.

Console

To filter resources by tag

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, select a resource type (for example, **Instances**).
3. Choose the search field.
4. In the list, under **Tags**, choose the tag key.
5. Choose the corresponding tag value from the list.
6. When you are finished, remove the filter.

For more information about using filters in the Amazon EC2 console, see Find your Amazon EC2 resources.

AWS CLI

To describe resources of a single type with the specified tag key

Add the following filter to a `describe` command to describe the resources of that type with a Stack tag, regardless of the value of the tag.

```
--filters Name=tag-key,Values=Stack
```

To describe resources of a single type with the specified tag

Add the following filter to a `describe` command to describe the resources of that type with the tag Stack=production.

```
--filters Name=tag:Stack,Values=production
```

To describe resources of a single type with the specified tag value

Add the following filter to a `describe` command to describe the resources of that type with a tag with the value production, regardless of the tag key.

```
--filters Name=tag-value,Values=production
```

To describe all EC2 resources with the specified tag

Add the following filter to the describe-tags command to describe all EC2 resources with the tag Stack=test.

```
--filters Name=key,Values=Stack Name=value,Values=test
```

PowerShell

To filter resources of a single type by tag key

Add the following filter to a `Get` cmdlet to describe the resources of that type with a Stack tag, regardless of the value of the tag.

```
-Filter @{Name="tag-key"; Values="Stack"}
```

To filter resources of a single type by tag

Add the following filter to a `Get` cmdlet to describe the resources of that type with the tag Stack=production.

```
-Filter @{Name="tag:Stack"; Values="production"}
```

To filter resources of a single type by tag value

Add the following filter to a `Get` cmdlet to describe the resources of that type with a tag with the value production, regardless of the value of the tag key.

```
-Filter @{Name="tag-value"; Values="production"}
```

To filter all EC2 resources by tag

Add the following filter to the Get-EC2Tag cmdlet to describe all EC2 resources with the tag Stack=test.

```
-Filter @{Name="tag:Stack"; Values="test"}
```

View tags for your EC2 instances using instance metadata

You can access an instance's tags from the instance metadata. By accessing tags from the instance metadata, you no longer need to use the `DescribeInstances` or `DescribeTags` API calls to retrieve tag information, which reduces your API transactions per second, and lets your tag retrievals scale with the number of instances that you control. Furthermore, local processes that are running on an instance can view the instance's tag information directly from the instance metadata.

By default, tags are not available from the instance metadata; you must explicitly allow access. You can allow access at instance launch, or after launch on a running or stopped instance. You can also allow access to tags by specifying this in a launch template. Instances that are launched by using the template allow access to tags in the instance metadata.

If you add or remove an instance tag, the instance metadata is updated while the instance is running, without needing to stop and then start the instance.

Tasks

- Enable access to tags in instance metadata
- Retrieve tags from instance metadata
- Disable access to tags in instance metadata

Enable access to tags in instance metadata

By default, there is no access to instance tags in the instance metadata. For each instance, you must explicitly enable access.

> **Note**
>
> If you allow access to tags in instance metadata, instance tag *keys* are subject to specific restrictions. Non-compliance will result in failed launches for new instances or an error for existing instances. The restrictions are:
>
> - Can only include letters (`a-z`, `A-Z`), numbers (`0-9`), and the following characters: `+ - = . , _ : @`.

- Can't contain spaces or /.
- Can't consist only of . (one period), .. (two periods), or _index.

For more information, see Tag restrictions.

Console

To enable access to tags in instance metadata during instance launch

1. Follow the procedure to launch an instance.
2. Expand **Advanced details**, and for **Allow tags in metadata**, choose **Enable**.
3. In the **Summary panel**, review your instance configuration, and then choose **Launch instance**. For more information, see Launch an EC2 instance using the launch instance wizard in the console.

To enable access to tags in instance metadata after instance launch

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance, and then choose **Actions**, **Instance settings**, **Allow tags in instance metadata**.
4. To allow access to tags in instance metadata, select the **Allow** checkbox.
5. Choose **Save**.

AWS CLI

To enable access to tags in instance metadata during instance launch

Use the run-instances command and add the following `--metadata-options` option.

```
--metadata-options "InstanceMetadataTags=enabled"
```

To enable access to tags in instance metadata after instance launch

Use the following modify-instance-metadata-options command.

```
aws ec2 modify-instance-metadata-options \
    --instance-id i-1234567890abcdef0 \
    --instance-metadata-tags enabled
```

To verify that access to tags in instance metadata is enabled

Use the describe-instances command and check the value of `InstanceMetadataTags`.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query "Reservations[*].Instances[].MetadataOptions[].InstanceMetadataTags"
```

The following is example output. The value is either `enabled` or `disabled`.

```
[
    "enabled"
]
```

PowerShell

To enable access to tags in instance metadata during instance launch

Use the New-EC2Instance cmdlet and add the following `-MetadataOptions_InstanceMetadataTags` parameter.

```
-MetadataOptions_InstanceMetadataTags enabled
```

To enable access to tags in instance metadata after instance launch

Use the Edit-EC2InstanceMetadataOption cmdlet.

```
Edit-EC2InstanceMetadataOption `
    -InstanceId i-1234567890abcdef0 `
    -InstanceMetadataTags enabled
```

To verify that access to tags in instance metadata is enabled

Use the Get-EC2Instance cmdlet and check the value of `InstanceMetadataTags`.

```
(Get-EC2Instance `
    -
InstanceId i-1234567890abcdef0).Instances.MetadataOptions.InstanceMetadataTags.Value
```

The following is example output. The value is either `enabled` or `disabled`.

```
enabled
```

Retrieve tags from instance metadata

After you allow access to instance tags in the instance metadata, you can access the `tags/instance` category from the instance metadata. For more information, see Access instance metadata for an EC2 instance.

IMDSv2

Linux

Run the following command from your Linux instance to list all the tag keys for the instance.

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
    && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/tags/instance
```

This example gets the value of a key obtained in the previous example. The IMDSv2 request uses the stored token that was created using the command in the previous example. The token must not be expired.

```
curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/tags/instance/tag-key
```

Windows

Run the following cmdlet from your Windows instance to list all the tag keys for the instance.

```
$token = Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} `
    -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token" = $token} `
    -Method GET -Uri http://169.254.169.254/latest/meta-data/tags/instance
```

This example gets the value of a key obtained in the previous example. The IMDSv2 request uses the stored token that was created using the command in the previous example. The token must not be expired.

```
Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token" = $token} `
    -Method GET -Uri http://169.254.169.254/latest/meta-data/tags/instance/tag-key
```

IMDSv1

Linux

Run the following command from your Linux instance to list all the tag keys for the instance.

```
curl http://169.254.169.254/latest/meta-data/tags/instance
```

This example gets the value of a key obtained in the previous example.

```
curl http://169.254.169.254/latest/meta-data/tags/instance/tag-key
```

Windows

Run the following cmdlet from your Windows instance to list all the tag keys for the instance.

```
Invoke-RestMethod -Uri http://169.254.169.254/latest/meta-data/tags/instance
```

This example gets the value of a key obtained in the previous example.

```
Invoke-RestMethod -Uri http://169.254.169.254/latest/meta-data/tags/instance/tag-key
```

Disable access to tags in instance metadata

You can disable access to instance tags in the instance metadata. You don't need to disable access to instance tags on instance metadata at launch because it's turned off by default.

Console

To disable access to tags in instance metadata

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and then choose **Actions**, **Instance settings**, **Allow tags in instance metadata**.
4. To turn off access to tags in instance metadata, clear the **Allow** checkbox.
5. Choose **Save**.

AWS CLI

To disable access to tags in instance metadata

Use the following modify-instance-metadata-options command.

```
aws ec2 modify-instance-metadata-options \
    --instance-id i-1234567890abcdef0 \
    --instance-metadata-tags disabled
```

PowerShell

To disable access to tags in instance metadata

Use the Edit-EC2InstanceMetadataOption cmdlet.

```
Edit-EC2InstanceMetadataOption `
    -InstanceId i-1234567890abcdef0 `
    -InstanceMetadataTag disabled
```

Amazon EC2 service quotas

When you create your AWS account, we set default *quotas* (also referred to as limits) on your AWS resources on a per-Region basis. If you attempt to exceed the quota for a resource, the request fails. For example, there is a maximum number of Amazon EC2 vCPUs that you can provision for On-Demand Instances in a Region. If you attempt to launch an instance in a Region and this

request would cause your usage to exceed this quota, the request fails. If this happens, you can reduce your resource usage or request a quota increase.

The Service Quotas console is a central location where you can view and manage your quotas for AWS services, and request a quota increase for many of the resources that you use. Use the quota information that we provide to manage your AWS infrastructure. Plan to request any quota increases in advance of the time that you'll need them.

View your current quotas

You can view your quotas for each Region using the Service Quotas console.

To view your current quotas using the Service Quotas console

1. Open the Service Quotas console at https://eusc-de-east-1.console.amazonaws-eusc.eu/servicequotas/home/services/ec2/quotas/.
2. From the navigation bar (at the top of the screen), select a Region.
3. On the **Manage quotas** pane, select a service; for example, **Amazon Elastic Compute Cloud (Amazon EC2)**. Choose **View quotas**.
4. Use the filter field to filter the list by resource name. For example, enter **`On-Demand`** to locate the quotas for On-Demand Instances.
5. To view more information, choose the quota name to open the details page for the quota.

Request an increase

You can request a quota increase for each Region.

To request an increase using the Service Quotas console

1. Open the Service Quotas console at https://eusc-de-east-1.console.amazonaws-eusc.eu/servicequotas/home/services/ec2/quotas/.
2. From the navigation bar (at the top of the screen), select a Region.
3. Use the filter field to filter the list by resource name. For example, enter **`On-Demand`** to locate the quotas for On-Demand Instances.
4. If the quota is adjustable, choose the quota and then choose **Request quota increase**.
5. For **Change quota value**, enter the new quota value.
6. Choose **Request**.

7. To view any pending or recently resolved requests in the console, choose **Dashboard** from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is **Pending**. After the status changes to **Quota requested**, you'll see the case number with Support. Choose the case number to open the ticket for your request.

For more information, including how to use the AWS CLI or SDKs to request a quota increase, see Requesting a quota increase in the *Service Quotas User Guide*.

Restriction on email sent using port 25

By default, Amazon EC2 allows outbound traffic over port 25 only to private IPv4 addresses. Traffic over port 25 is blocked to public IPv4 addresses and IPv6 addresses.

You can request that this restriction be removed. For more information, see How do I remove the restriction on port 25 from my Amazon EC2 instance or Lambda function?

This restriction does not apply to outbound traffic over port 25 destined for:

For IPv4:

- IP addresses in the primary CIDR block of the VPC in which the originating network interface exists.
- IP addresses in the CIDRs defined in RFC 1918 and RFC 6598.

For IPv6:

- IP addresses in the subnet CIDR block in which the originating network interface exists.
- IP addresses in the CIDRs defined in RFC 4193.
- In the China Regions (Beijing (cn-north-1), Ningxia (cn-northwest-1)), IP addresses in all CIDR blocks associated with the VPC in which the originating network interface exists.

Monitor Amazon EC2 resources

Monitoring is an important part of maintaining the reliability, availability, and performance of your Amazon EC2 instances and your AWS solutions. You should collect monitoring data from all of the parts in your AWS solutions so that you can more easily debug a multi-point failure if one occurs.

AWS provides various tools that you can use to monitor Amazon EC2. The Amazon EC2 and CloudWatch console dashboards provide an at-a-glance view of the state of your Amazon EC2 environment. In addition, we provide the following:

- **System status checks** – Monitor the AWS systems required to use your instance to ensure that they are working properly. These checks detect problems with your instance that require AWS involvement to repair. When a system status check fails, you can choose to wait for AWS to fix the issue or you can resolve it yourself (for example, by stopping and restarting or terminating and replacing an instance). Examples of problems that cause system status checks to fail include:
  - Loss of network connectivity
  - Loss of system power
  - Software issues on the physical host
  - Hardware issues on the physical host that impact network reachability

  For more information, see Status checks for Amazon EC2 instances.
- **Instance status checks** – Monitor the software and network configuration of your individual instance. These checks detect problems that require your involvement to repair. When an instance status check fails, typically you will need to address the problem yourself (for example, by rebooting the instance or by making modifications in your operating system). Examples of problems that may cause instance status checks to fail include:
  - Failed system status checks
  - Misconfigured networking or startup configuration
  - Exhausted memory
  - Corrupted file system
  - Incompatible kernel

  For more information, see Status checks for Amazon EC2 instances.
- **Amazon CloudWatch alarms** – Watch a single metric over a time period you specify, and perform one or more actions based on the value of the metric relative to a given threshold over

a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms will not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see Monitor your instances using CloudWatch.

- **Amazon EventBridge events** – Automate your AWS services and respond automatically to system events. Events from AWS services are delivered to EventBridge in near real time, and you can specify automated actions to take when an event matches a rule you write. For more information, see the section called "Automate using EventBridge".
- **AWS CloudTrail logs** – Capture detailed information about the calls made to the Amazon EC2 API and stores them as log files in Amazon S3. You can use CloudTrail logs to determine which calls were made, the source IP address for the call, who made the call, and when the call was made. For more information, see the section called "Log API calls using CloudTrail".
- **CloudWatch agent** – Collect logs and system-level metrics from both hosts and guests on your EC2 instances and on-premises servers. For more information, see Collecting Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the *Amazon CloudWatch User Guide*.

Monitor the status of your Amazon EC2 instances

You can monitor the status of your instances by viewing status checks and scheduled events for your instances.

A status check gives you the information that results from automated checks performed by Amazon EC2. These automated checks detect whether specific issues are affecting your instances. The status check information, together with the data provided by Amazon CloudWatch, gives you detailed operational visibility into each of your instances.

You can also see the status of specific events that are scheduled for your instances. The status of events provides information about upcoming activities that are planned for your instances, such as rebooting or retirement. They also provide the scheduled start and end time of each event.

- Scheduled events for Amazon EC2 instances

Status checks for Amazon EC2 instances

With status checks, you can quickly determine whether there are problems that might prevent your instances from running your applications. Amazon EC2 provides four types of status checks: system, instance, attached EBS, and application. System, instance, and attached EBS status checks are managed by Amazon EC2 and run automatically on every instance. Application status checks are opt-in and monitor the HTTP or HTTPS responses of applications running on your instances. You can view the results of all status checks in the Amazon EC2 console, the AWS CLI, or the AWS SDKs.

Status checks are performed every minute, returning a pass or a fail status. If all checks pass, the overall status of the instance is **OK**. If one or more checks fail, the overall status is **impaired**. System, instance, and attached EBS status checks are managed by Amazon EC2 and cannot be disabled or deleted. Application status checks are opt-in; you create, associate, and manage them yourself.

When a status check fails, the corresponding CloudWatch metric for status checks is incremented. For more information, see Status check metrics. You can use these metrics to create CloudWatch alarms that are triggered based on the result of the status checks. For example, you can create an alarm to warn you if status checks fail on a specific instance. For more information, see Create CloudWatch alarms for Amazon EC2 instances that fail status checks.

You can also create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying issue. For more information, see Automatic instance recovery.

Contents

- Types of status checks
- View status checks for Amazon EC2 instances
- Create CloudWatch alarms for Amazon EC2 instances that fail status checks

Types of status checks

There are four types of status checks.

- System status checks

- Instance status checks
- Attached EBS status checks
- Application status checks

System status checks

System status checks monitor the AWS systems on which your instance runs. These checks detect underlying problems with your instance that require AWS involvement to repair. When a system status check fails, you can choose to wait for AWS to fix the issue, or you can resolve it yourself. For instances backed by Amazon EBS, you can stop and start the instance yourself, which in most cases results in the instance being migrated to a new host. For instances backed by instance store (supported only for Linux instances), you can terminate and replace the instance. Note that instance store volumes are ephemeral and all data is lost when the instance is stopped.

The following are examples of problems that can cause system status checks to fail:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

If a system status check fails, we increment the StatusCheckFailed_System metric.

Bare metal instances

If you perform a restart on a bare metal instance, the system status check might temporarily return a fail status. When the instance becomes available, the system status check should return a pass status.

Instance status checks

Instance status checks monitor the software and network connectivity of your individual instance. Amazon EC2 checks the health of the instance by sending an address resolution protocol (ARP) request to the network interface (NIC). These checks detect problems that require your involvement to repair. When an instance status check fails, you typically must address the problem yourself (for example, by rebooting the instance or by making instance configuration changes).

> **Note**
>
> Recent Linux distributions that use `systemd-networkd` for network configuration might report on health checks differently from earlier distributions. During the boot process, this type of network can start earlier and potentially finish before other startup tasks that can also affect instance health. Status checks that depend on network availability can report a healthy status before other tasks complete.

The following are examples of problems that can cause instance status checks to fail:

- Failed system status checks
- Incorrect networking or startup configuration
- Exhausted memory
- Corrupted file system
- Incompatible kernel
- During a reboot, an instance status check can report a failure until the instance becomes available again.

If an instance status check fails, we increment the StatusCheckFailed_Instance metric.

Bare metal instances

If you perform a restart on a bare metal instance, the instance status check might temporarily return a fail status. When the instance becomes available, the instance status check should return a pass status.

Attached EBS status checks

Attached EBS status checks monitor if the Amazon EBS volumes attached to an instance are reachable and able to complete I/O operations. The `StatusCheckFailed_AttachedEBS` metric is a binary value that indicates impairment if one or more of the EBS volumes attached to the instance are unable to complete I/O operations. These status checks detect underlying issues with the compute or Amazon EBS infrastructure. When the attached EBS status check metric fails, you can either wait for AWS to resolve the issue, or you can take actions, such as replacing the affected volumes or stopping and restarting the instance.

The following are examples of issues that can cause attached EBS status checks to fail:

- Hardware or software issues on the storage subsystems underlying the EBS volumes
- Hardware issues on the physical host that impact reachability of the EBS volumes
- Connectivity issues between the instance and EBS volumes

You can use the `StatusCheckFailed_AttachedEBS` metric to help improve the resilience of your workload. You can use this metric to create Amazon CloudWatch alarms that are triggered based on the result of the status check. For example, you could fail over to a secondary instance or Availability Zone when you detect a prolonged impact. Alternatively, you can monitor the I/O performance of each attached volume using EBS CloudWatch metrics to detect and replace the impaired volume. If the EBS status check indicates an impairment and your workload isn't driving I/O to attached EBS volumes, stop and start the instance to move it to a new host. This can resolve underlying host issues that are impacting the reachability of the EBS volumes. For more information, see Amazon CloudWatch metrics for Amazon EBS.

You can also configure your Amazon EC2 Auto Scaling groups to detect attached EBS status check failures, and then replace the affected instance with a new one. For more information, see Monitor and replace Auto Scaling instances with impaired Amazon EBS volumes in the *Amazon EC2 Auto Scaling User Guide*.

> **Note**
>
> The attached EBS status check metric is available only for Nitro instances.

Application status checks

Use application status checks to monitor the network reachability and availability of applications running on your Amazon EC2 instances. With application status checks, you can monitor HTTP and HTTPS responses at the application level. Application status checks run only on instances you associate them with.

You configure each application status check to request an HTTP path on your application endpoint and define the response codes that indicate a healthy response.

You can suppress application status checks during application restarts or deployments to avoid false-positive failures during expected downtime. For more information, see Handling deployment, in-place patching, and replacements.

The following are examples of problems that can cause application status checks to fail:

- Application process crashed or stopped responding
- Application returned an HTTP response code indicating an internal application service error or other problem
- Application port not reachable
- A software or underlying hardware issue has caused your instance to fail and become unresponsive

If an application status check fails, we increment the `StatusCheckFailed_Application` metric.

For information about configuring application status checks, see Application status checks.

View status checks for Amazon EC2 instances

If your instance has a failed status check, you typically must address the problem yourself (for example, by rebooting the instance or by making instance configuration changes). To troubleshoot system or instance status check failures yourself, see Troubleshoot Amazon EC2 Linux instances with failed status checks.

Console

To view status checks

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. On the **Instances** page, the **Status check** column lists the operational status of each instance.
4. To view the status of a specific instance, select the instance, and then choose the **Status and alarms** tab.
5. To review the CloudWatch metrics for status checks, on the **Status and alarms** tab, expand **Metrics** to see the graphs for the following metrics:
   - **Status check failed for system**
   - **Status check failed for instance**
   - **Status check failed for attached EBS**
   - **Status check failed for application**

For more information, see the section called "Status check metrics".

AWS CLI

To view status checks

Use the describe-instance-status command.

Example: Get the status of all running instances

```
aws ec2 describe-instance-status
```

Example: Get the status of all instances

```
aws ec2 describe-instance-status --include-all-instances
```

Example: Get the status of a single running instance

```
aws ec2 describe-instance-status --instance-ids i-1234567890abcdef0
```

Example: Get all instances with a status of `impaired`

```
aws ec2 describe-instance-status \
--filters Name=instance-status.status,Values=impaired
```

PowerShell

To view status checks

Use the Get-EC2InstanceStatus command.

Example: Get the status of all running instances

```
Get-EC2InstanceStatus
```

Example: Get the status of all instances

```
Get-EC2InstanceStatus -IncludeAllInstance $true
```

Example: Get the status of a single running instance

```
Get-EC2InstanceStatus -InstanceId i-1234567890abcdef0
```

Example: Get all instances with a status of `impaired`

```
Get-EC2InstanceStatus \
-Filter @{Name="instance-status.status"; Values="impaired"}
```

Create CloudWatch alarms for Amazon EC2 instances that fail status checks

You can use the status check metrics to create CloudWatch alarms to notify you when an instance has a failed status check.

Status checks and status check alarms can temporarily enter an *insufficient data* state if there are missing metric data points. Although rare, this can happen when there is an interruption in the metric reporting systems, even when an instance is healthy. We recommend that you treat this state as missing data instead of a status check failure or alarm breach. This is especially important when taking stop, terminate, reboot, or recover actions on the instance in response.

Console

This example configures an alarm that sends a notification when an instance fails a status check. You can optionally stop, terminate, or recover the instance.

To create a status check alarm

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance, choose the **Status Checks** tab, and choose **Actions**, **Create status check alarm**.
4. On the **Manage CloudWatch alarms** page, under **Add or edit alarm**, choose **Create an alarm**.
5. For **Alarm notification**, turn the toggle on to configure Amazon Simple Notification Service (Amazon SNS) notifications. Select an existing Amazon SNS topic or enter a name to create a new topic.

If you add an email address to the list of recipients or create a new topic, Amazon SNS sends a confirmation email to each new address. Each recipient must choose the confirmation link in the email. Only confirmed addresses receive alert notifications.

6. For **Alarm action**, turn the toggle on to specify an action to take when the alarm is triggered. Select the action.
7. For **Alarm thresholds**, specify the metric and criteria for the alarm.

   You can leave the default settings for **Group samples by** (**Average**) and **Type of data to sample** (**Status check failed:either**), or you can change them to suit your needs.

   For **Consecutive period**, set the number of periods to evaluate and, in **Period**, enter the evaluation period duration before triggering the alarm and sending an email.
8. (Optional) For **Sample metric data**, choose **Add to dashboard**.
9. Choose **Create**.

If you need to change an instance status alarm, you can edit it.

To edit a status check alarm

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitoring**, **Manage CloudWatch alarms**.
4. On the **Manage CloudWatch alarms** page, under **Add or edit alarm**, choose **Edit an alarm**.
5. For **Search for alarm**, choose the alarm.
6. When you are finished making changes, choose **Update**.

AWS CLI

In the following example, the alarm publishes a notification to an SNS topic when the instance fails either the instance check or system status check for at least two consecutive periods. The CloudWatch metric used is `StatusCheckFailed`.

To create a status check alarm

1. Select an existing SNS topic or create a new one. For more information, see Accessing Amazon SNS in the AWS CLI in the *AWS Command Line Interface User Guide*.

2. Use the following list-metrics command to view the available Amazon CloudWatch metrics for Amazon EC2.

```
aws cloudwatch list-metrics --namespace AWS/EC2
```

3. Use the following put-metric-alarm command to create the alarm.

```
aws cloudwatch put-metric-alarm \
    --alarm-name StatusCheckFailed-Alarm-for-i-1234567890abcdef0 \
    --metric-name StatusCheckFailed \
    --namespace AWS/EC2 \
    --statistic Maximum \
    --dimensions Name=InstanceId,Value=i-1234567890abcdef0 \
    --unit Count \
    --period 300 \
    --evaluation-periods 2 \
    --threshold 1 \
    --comparison-operator GreaterThanOrEqualToThreshold \
    --alarm-actions arn:aws-eusc:sns:us-west-2:111122223333:my-sns-topic
```

The period is the time frame, in seconds, in which Amazon CloudWatch metrics are collected. This example uses 300, which is 60 seconds multiplied by 5 minutes. The evaluation period is the number of consecutive periods for which the value of the metric must be compared to the threshold. This example uses 2. The alarm actions are the actions to perform when this alarm is triggered.

PowerShell

To create a status check alarm

Use the Write-CWMetricAlarm cmdlet as follows to publish notifications to an SNS topic when the instance fails status checks for at least two consecutive periods.

```
Write-CWMetricAlarm `
    -AlarmName "StatusCheckFailed-Alarm-for-i-1234567890abcdef0" `
    -MetricName "StatusCheckFailed" `
    -Namespace "AWS/EC2" `
    -Statistic "Maximum" `
    -Dimension @{Name="InstanceId"; Values="i-1234567890abcdef0"} `
    -Unit "Count" `
    -Period 300 `
```

```
    -EvaluationPeriod 2 `
    -Threshold 1 `
    -ComparisonOperator "GreaterThanOrEqualToThreshold" `
    -AlarmAction "arn:aws-eusc:sns:us-west-2:111122223333:my-sns-topic"
```

The period is the time frame, in seconds, in which Amazon CloudWatch metrics are collected. This example uses 300, which is 60 seconds multiplied by 5 minutes. The evaluation period is the number of consecutive periods for which the value of the metric must be compared to the threshold. This example uses 2. The alarm actions are the actions to perform when this alarm is triggered.

Application status checks

Application status checks help you monitor the performance and health of your applications running on Amazon EC2. With application status checks, you can detect and respond to application health impairments by monitoring your applications through configurable paths and ports. For example, you can use application status checks to confirm that your web server is listening on its expected port and accepting new connections.

Application status checks monitor the HTTP and HTTPS responses of your applications at configurable paths and ports. They run every 60 seconds and integrate with Amazon EC2 Auto Scaling, so you can automate replacement of instances whose applications are impaired.

How application status checks work

Application status checks send HTTP or HTTPS requests to an endpoint listening at a network port on your instance every 60 seconds. AWS compares the response code against the status code matcher you configured. The check is marked impaired after a number of consecutive failed requests, and healthy again after a number of consecutive successful requests. Both counts default to 2 and are configurable. For more information, see Evaluation thresholds.

> **Note**
>
> Application status checks send the health check request over HTTP/2.
> The HTTPS protocol check does not validate the server certificate.

During a reboot, application status checks report a failure until the instance becomes available again because the application cannot respond to health check requests while the operating system is restarting.

Network architecture

Application status checks originate from the Amazon EC2 application status checks service. To reach your instances, AWS creates a managed elastic network interface (ENI) in your VPC. AWS creates one ENI per combination of source subnet and security group that has associated instances. AWS creates the managed ENI when an application status check first requires that combination, and removes it when no remaining application status check requires it. The managed ENI does not count against your instance ENI limit, but does count against the *Network interfaces per Region* quota for your account, which is enforced per Availability Zone. For more information, see Amazon VPC quotas.

By default, Amazon EC2 hides these managed network interfaces from the console and API list operations for accounts that did not have managed resources before this setting became available. To change their visibility, see Managed resource visibility settings.

AWS creates one managed network interface for each combination of source subnet and security group among your associated instances. The number of managed interfaces grows with the

number of distinct subnet and security group combinations your monitored instances use. Consolidating monitored instances into fewer subnet and security group combinations reduces the number of managed interfaces. For example, 200 instances spread across 2 subnets that all use a single security group produce 2 managed interfaces. The same 200 instances using 3 security groups across those 2 subnets produce up to 6 managed interfaces. Each interface corresponds to one subnet and security group combination.

Application status checks reach your instances from a private vantage point within your VPC. The scope describes where the check originates, not a property of your instance's IP address. AWS creates the managed ENI in a subnet within your VPC and reaches the instance over the private network path.

With AWS managed network paths, health check traffic originates from AWS managed Amazon EC2 instances in the same Availability Zone as the target instance (or the parent Availability Zone for Local Zone targets). The traffic travels over the AWS internal network and does not traverse the public internet. For more information, see Amazon VPC FAQs on the Amazon Web Services website.

With customer-managed network paths, you choose the source subnets, so you can run checks from a different Availability Zone than the target. For more information, see the section called “Cross-Availability Zone monitoring”.

AWS managed and customer-managed network paths

Application status checks support two onboarding modes that determine who selects the source subnets and security groups for the health check ENI and the destination subnets and security groups for the target instances.

AWS managed network paths

: AWS selects the source subnets and security groups for the health check ENI and the destination subnets and security groups for the target instances.

Customer-managed network paths

: You specify the source subnets and security groups for the health check ENI and the destination subnets and security groups for the target instances.

  Use customer-managed network paths when you need to control which subnets and security groups health check traffic originates from, such as when your VPC has strict network segmentation, firewall rules, or compliance requirements that restrict which sources can reach your application endpoints.

You choose the mode by including or omitting the `--health-check-paths` parameter in the create command. If you omit the `--health-check-paths` parameter, AWS selects source and destination subnets and security groups (AWS managed network paths). If you include the `--health-check-paths` parameter, you manage them (customer-managed network paths).

IP version

Each application status check is associated with a single IP version (IPv4 or IPv6). To monitor an instance over both IPv4 and IPv6, create two separate application status checks and associate both with the instance.

Checks reach your instance from within your VPC for both IPv4 and IPv6.

Check status values

Each individual check reports one of the following statuses:

- `passed`: the check completed successfully
- `failed`: the check failed. The response includes the HTTP status code returned by your application. For interpretation and remediation guidance, see Troubleshooting.
- `initializing`: the check has not yet completed its first evaluation
- `insufficient-data`: the check did not receive enough data to determine a result
- `not-applicable`: the check is not associated with the instance

The overall application status reported for the instance aggregates all individual check results. The overall status is one of the following:

- ok: all checks passed
- `impaired`: one or more checks failed
- `initializing`: one or more checks have not yet completed their first evaluation
- `insufficient-data`: one or more checks report insufficient data
- `not-applicable`: all associated application status checks are excluded from aggregation
- `suppressed`: application status check evaluation is suppressed for the instance

Aggregation

You can mark each application status check as included in or excluded from the overall status for the instance. By default, a check is `included`.

`included`

The check contributes to the overall status for the instance and Amazon EC2 Auto Scaling uses it.

`excluded`

The check reports its individual status but does not contribute to the overall status for the instance and Amazon EC2 Auto Scaling does not use it. Use this setting to validate a new check in production without affecting the overall status or triggering Amazon EC2 Auto Scaling replacements. This is the recommended workflow when adding a check to an existing production workload; see Testing a new application status check.

Get started with application status checks

Prerequisites

Before you create an application status check, make sure you have the following:

- A VPC with the instances you want to monitor.
- An application endpoint on each instance that can respond to HTTP or HTTPS requests on the port and HTTP path you will configure.
- A security group on each destination instance that allows inbound traffic on the check port from the source security group used by the application status check. See Security and permissions.

Step 1: Configure your application

Configure your application endpoint to respond to HTTP or HTTPS requests on the port and HTTP path you will specify when you create the check. Return a response code included in your status code matcher to indicate the application is healthy.

Make sure the destination instance's security group allows inbound traffic on the check port from the source security group used by the application status check. For managed network paths, AWS provides the source security group at check creation. For customer-managed network paths, you specify the source security group when you create the check.

Step 2: Create a check definition

Use the AWS CLI to create an application status check.

Console

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Choose **Actions**, **Monitor and troubleshoot**, **Monitor**, **Application status checks**.
4. Choose **Create application status check**.
5. Under **Health check logic**, configure the following:
   - **Protocol**: choose **HTTP** or **HTTPS**.
   - **Port**: enter the port on which your application listens.
   - **Path** (optional): enter the HTTP path to request, for example `/healthcheck`.
   - **IP version**: choose **IPv4** or **IPv6**.
   - **Device index**: the network interface device index to check. Default is `0`.
6. Under **Controls and thresholds**, set the **Timeout**, and optionally the **Status code matcher**, **Failure threshold**, **Success threshold**, and **Initialization grace period**. The check interval is fixed at 60 seconds.
7. Under **Aggregation**, choose **Included** for the check to contribute to the overall application status and drive Amazon EC2 Auto Scaling, or **Excluded** to report the check without affecting the overall status.
8. Under **Health check paths**, keep **Do not specify network paths (recommended/default)** to let Amazon EC2 place the health check network interfaces in your instance's subnets, or choose **Specify network paths (advanced)** to define the source subnet, security group, and destinations yourself.
9. (Optional) Add a **Name tag** and other **Tags**.
10. Choose **Create application status check**.

AWS CLI

To use AWS managed network paths, omit the `--health-check-paths` parameter and let AWS select source and destination subnets and security groups.

```
aws ec2 create-application-status-check \
```

```
        --protocol https \
        --port 443 \
        --path "/health" \
        --status-code-matcher "200"
```

To use customer-managed network paths, include the `--health-check-paths` parameter. Each health check path contains a source (subnet and security group for the health check ENI) and one or more destinations (subnet and security group for the target instances).

```
aws ec2 create-application-status-check \
        --protocol https \
        --port 443 \
        --path "/health" \
        --status-code-matcher "200" \
        --health-check-paths '[{"Source":
{"SubnetId":"subnet-111","SecurityGroupId":"sg-aaa"},"Destinations":
[{"SubnetId":"subnet-222","SecurityGroupId":"sg-bbb"}]}]'
```

Step 3: Associate the check with instances

Associate the check with the instances you want to monitor, either by instance ID or by tag.

Console

1. In the navigation pane, choose **Instances**.
2. Choose **Actions**, **Monitor and troubleshoot**, **Monitor**, **Application status checks**.
3. Select the check.
4. Choose **Manage status check associations**, then choose **Manage associations by resource ID** or **Manage associations by tags**.
5. To associate with all instances in an Auto Scaling group, choose **Manage associations by tags** and enter `aws:autoscaling:groupName` as the tag key and your Auto Scaling group name as the value.
6. Choose **Associate**.

AWS CLI

By instance ID:

```
aws ec2 associate-application-status-check \
        --application-status-check-id asc-1234567890abcdef0 \
        --instance-ids i-0123456789abcdef0
```

By tag:

```
aws ec2 associate-application-status-check \
        --application-status-check-id asc-1234567890abcdef0 \
        --target-tag-associations Key=Environment,Value=production
```

To associate with all instances in an Auto Scaling group, use the `aws:autoscaling:groupName` system tag:

```
aws ec2 associate-application-status-check \
        --application-status-check-id asc-1234567890abcdef0 \
        --target-tag-associations Key=aws:autoscaling:groupName,Value=my-asg
```

Associate and disassociate operations return per-instance success and failure results. If some instances cannot be associated (for example, because the check is already associated), those instances appear in the unsuccessful results with a reason.

Step 4: View results

View the per-instance application health status.

Console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and then choose the **Status and alarms** tab.
4. Under **Application status checks**, review the overall status and each associated check's individual status.

AWS CLI

```
aws ec2 describe-application-status \
        --instance-ids i-0123456789abcdef0
```

The response includes the overall application status and, for each associated check, the check status and, for failed checks, the HTTP status code returned by your application.

Example response:

```
{
        "ApplicationStatuses": [
            {
                "InstanceId": "i-0123456789abcdef0",
                "ApplicationStatus": {
                    "Status": "ok",
                    "Details": [
                        {
                            "ApplicationStatusCheckId": "asc-1234567890abcdef0",
                            "Status": "passed",
                            "Reason": {
                                "Code": "ResponseCodeMatched",
                                "StatusCode": 200,
                                "Protocol": "HTTP"
                            }
                        }
                    ]
                }
            }
        ]
    }
```

To view check definitions (not per-instance status), use describe-application-status-checks. This command returns the configuration of your application status checks, including protocol, port, HTTP path, and status code matcher settings.

Configuration options

Application status checks accept several configuration parameters. This section explains the parameters where the behavior isn't self-evident from the parameter name. For the complete list of parameters and validation rules, see CreateApplicationStatusCheck and AssociateApplicationStatusCheck in the *Amazon EC2 API Reference*.

Evaluation thresholds

`FailureThreshold`

The number of consecutive failed requests before the check is marked impaired. Default: 2.

`SuccessThreshold`

The number of consecutive successful requests before the check is marked healthy again. Default: 2.

`Timeout`

The number of seconds to wait for a response before the request is recorded as failed. Enforced as a forced timeout; if your application does not respond within this window, the request is recorded as a failure regardless of eventual response. Default: 6. Valid range: 1-30.

Startup grace period

`InitializationGracePeriodSeconds`

The number of seconds to wait after an instance launches before AWS starts evaluating the check. Use this parameter to give applications time to start listening before checks begin. If the grace period is too short, Amazon EC2 Auto Scaling might replace new instances before their application is ready. Default: 300. Valid range: 1 to 600.

IP scope

`IpScope`

Application status checks use `private` scope; the check runs from within your VPC. For IPv4, this corresponds to the instance's private IP address. For IPv6, AWS does not classify the address as public or private; the check accepts any IPv6 address and evaluates it from within your VPC.

Device index

`DeviceIndex`

The index of the network device on your instance that AWS evaluates for the health check. Change this when your instance's primary network device is not the one you want checked. Default: 0.

Aggregation, IP version, and health check paths (source and destination subnets and security groups) are covered in their own sections earlier on this page.

Default settings

With AWS managed network paths, application status checks use the following defaults.

Setting	Default
Check interval	60 seconds (fixed; not configurable)
Failure threshold	2 consecutive failures
Success threshold	2 consecutive successes
Timeout	6 seconds
Status code matcher	200
HTTP path	/
IP version	ipv4
IP scope	private
Device index	0
Initialization grace period	300 seconds
Aggregation	included
Source subnets and security groups	Managed by AWS

Amazon EC2 Auto Scaling integration

Amazon EC2 Auto Scaling automatically terminates and replaces instances whose overall application status reports `impaired`, as long as the check is included in aggregation. No Auto Scaling group configuration is required beyond associating the application status check with the instances in the group.

Amazon EC2 Auto Scaling uses the overall status for the instance, not individual check status. Checks marked `excluded` do not drive Amazon EC2 Auto Scaling actions. Checks in the `suppressed` state do not drive Amazon EC2 Auto Scaling actions.

Use the `InitializationGracePeriodSeconds` parameter on the check to allow new instances time to start up before application status checks begin. If the grace period is too short, new instances might be terminated and replaced by Amazon EC2 Auto Scaling before their application is ready to serve traffic.

The check's `InitializationGracePeriodSeconds` sets how long after an instance launches before the check starts evaluating the application. Set it to cover your application's startup time, so the check does not report `impaired` while the application is still starting up. The Auto Scaling group's health check grace period is separate. It sets how long after an instance enters service before Amazon EC2 Auto Scaling terminates it for a failed health check.

For more information about how Amazon EC2 Auto Scaling uses health checks, see Health checks for instances in an Auto Scaling group and Use application status checks with an Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.

Handling deployment, in-place patching, and replacements

Deployments, in-place patching, and other maintenance operations can temporarily stop or restart your application. During that time, application status checks report a failure because the application cannot respond to health check requests. If your instances are in an Auto Scaling group with application status checks included in aggregation, Amazon EC2 Auto Scaling might terminate and replace these instances even though the disruption is expected.

Option A: Suppress the check

Use suppression for bounded maintenance windows where you know the duration. Suppression is enforced at the instance level. You specify a duration, or omit it to suppress the check until you disable the suppression.

AWS CLI

```
aws ec2 enable-application-status-check-suppression \
        --instance-ids i-0123456789abcdef0 \
        --duration-seconds 3600
```

The response returns, for each instance, when suppression started and when it will end. Partial success is possible; some instances may fail to be suppressed and appear in the response with a reason.

To resume checks before the suppression window expires:

```
aws ec2 disable-application-status-check-suppression \
        --instance-ids i-0123456789abcdef0
```

While suppressed, the overall application status for the instance reports `suppressed`. Amazon EC2 Auto Scaling does not act on `suppressed` instances.

Option B: Exclude the check from aggregation

If you want the check to keep evaluating and reporting its individual status but not affect the overall status or trigger Amazon EC2 Auto Scaling actions, set the check's aggregation setting to `excluded`. This is useful for longer-lived scenarios such as rolling out a new check version or validating a change without risking replacement, and for cases where you want telemetry to continue without operational impact.

For more information, see Aggregation.

Option C: Disassociate the check

Use disassociation for longer-lived or indefinite removal.

```
aws ec2 disassociate-application-status-check \
        --application-status-check-id asc-1234567890abcdef0 \
        --instance-ids i-0123456789abcdef0
```

If you associated by tag, remove the tag from the instance to disassociate. After disassociation, the overall application status for the instance reports `not-applicable`.

Deployment guidance

Deployments are the most common maintenance scenario that requires suppression. Use suppression when your deployment tool has a pre-deployment hook and a post-deployment hook so that you can suppress the check before the deployment starts and disable suppression after the deployment completes.

The general pattern is:

1. In the pre-deployment hook, call enable-application-status-check-suppression for the instance, with a duration that covers the expected deployment window.
2. Perform the deployment.
3. In the post-deployment hook, call disable-application-status-check-suppression for the instance.

If your deployment tool does not have hooks, drive suppression from the CI/CD pipeline that invokes the deployment.

Testing a new application status check

You can validate a new application status check in production before it starts contributing to your instance-level monitoring. Set the aggregation setting to `excluded` when you create the check, then confirm it reports the expected status and HTTP response codes. When you're ready, change the setting to `included` so the check contributes to the overall status for the instance and integrates with Amazon EC2 Auto Scaling.

1. Create the check with the aggregation setting set to `excluded`.

```
aws ec2 create-application-status-check \
        --protocol https \
        --port 443 \
        --path "/health" \
        --status-code-matcher "200" \
        --aggregation excluded
```

2. Associate the check with a test instance or a subset of your production fleet.
3. Wait for at least two check intervals (approximately two minutes) to allow the check to complete an initial evaluation.
4. Use describe-application-status to verify the check is reporting the expected status and HTTP response code.

```
aws ec2 describe-application-status \
        --instance-ids i-0123456789abcdef0
```

5. If the check reports as expected, update the aggregation setting to `included` to make the check contribute to the overall status for the instance and drive Amazon EC2 Auto Scaling actions.

```
aws ec2 modify-application-status-check \
```

```
        --application-status-check-id asc-1234567890abcdef0 \
        --aggregation included
```

Advanced networking

Application status checks originate from a managed ENI in the source subnet and security group you specify (or that AWS selects for you). For workloads that require higher availability than a single-source configuration provides, or for workloads that run in Local Zones or Outposts, consider the following patterns.

Cross-Availability Zone monitoring

For Availability Zone redundancy, you can run health checks from more than one Availability Zone. With customer-managed network paths, you define health check paths whose sources are in two different Availability Zones that reach the same destination instances, using the `--health-check-paths` parameter. Monitoring from two Availability Zones keeps health reporting for your instances continuous even if one Availability Zone becomes unavailable.

The following example creates a check with two health check paths whose sources are in different Availability Zones, both reaching the same destination instances.

```
aws ec2 create-application-status-check \
        --protocol https \
        --port 443 \
        --path "/health" \
        --status-code-matcher "200" \
        --health-check-paths '[{"Source":{"SubnetId":"subnet-source-
az1","SecurityGroupId":"sg-healthcheck"},"Destinations":[{"SubnetId":"subnet-
app-az1","SecurityGroupId":"sg-app"}]},{"Source":{"SubnetId":"subnet-source-
az2","SecurityGroupId":"sg-healthcheck"},"Destinations":[{"SubnetId":"subnet-app-
az2","SecurityGroupId":"sg-app"}]}]'
```

Local Zones

For instances running in AWS Local Zones, the managed elastic network interface (ENI) resides in the parent AWS Region, not in the Local Zone. Health check traffic between the parent Region and your Local Zone instances traverses the Local Zone service link, which may incur additional data transfer charges.

Best practices

- **Design your health endpoint to reflect the health of the application running on that instance.** When your endpoint returns health based on the application itself, Amazon EC2 Auto Scaling replaces only the instances that are genuinely impaired. If the endpoint's response also depends on a shared resource such as a database or a downstream service, a problem with that resource can fail the check across many instances at once. This can trigger a fleet-wide replacement. For guidance on writing health check endpoints, see Implementing health checks in the Amazon Builders' Library.
- **Protect against correlated failures.** An included check drives Amazon EC2 Auto Scaling replacement. A check that fails across many instances at once can trigger a wave of replacements. Set an instance maintenance policy on your Auto Scaling group to limit how many instances are replaced at the same time. For more information, see Instance maintenance policy in the *Amazon EC2 Auto Scaling User Guide* .
- **Alarm on the count of impaired instances.** Create an Amazon CloudWatch alarm on the `StatusCheckFailed_Application` metric across your fleet. A sudden rise across many instances indicates a shared dependency rather than individual instance faults, and gives you time to respond before replacements cascade. For more information, see the section called "Monitor application status checks".
- **Stay within your network interface quota.** Application status checks create managed network interfaces that count against the *Network interfaces per Region* quota. AWS enforces this quota per Availability Zone. Monitor your usage so a growing fleet does not reach the quota. If it does, AWS cannot create new interfaces. For related quota alarm guidance, see the section called "Quotas".
- **Treat status check permissions as change-controlled.** The IAM actions that create, modify, delete, associate, disassociate, and suppress application status checks can affect instance availability. These actions determine what drives Amazon EC2 Auto Scaling replacement. Treat actions such as `ec2:CreateApplicationStatusCheck`, `ec2:AssociateApplicationStatusCheck`, `ec2:ModifyApplicationStatusCheck`, and `ec2:EnableApplicationStatusCheckSuppression` as change-controlled rather than granting them as part of general Amazon EC2 access. For the full list of actions, see the Amazon EC2 API Reference.

Troubleshooting

When an application status check reports impaired but you expect your application to be healthy, verify each of the following:

1. *Instance reachability.* Confirm that the instance's Instance and System status checks are ok.
2. *Security group inbound rule.* The destination instance's security group must allow inbound traffic on the check port from the source security group used by the application status check. For AWS managed network paths, AWS provides the source security group; for customer-managed network paths, use the security group you specified as the source.
3. *Host firewall.* Any host-level firewall (iptables, Windows Firewall, third-party host firewall) on the instance must allow inbound traffic on the check port.
4. *Application endpoint.* The application must be listening on the port and path you configured. Confirm with a local request from the instance (`curl http://localhost:PORT/PATH`).
5. *Protocol mismatch.* If the check is configured as HTTPS but the endpoint serves HTTP only (or vice versa), all calls will fail.
6. *Status code matcher.* Confirm that your application's actual response code is included in the status code matcher you configured.
7. *Network path.* If you configured customer-managed network paths, confirm the source subnet and security group have connectivity to the destination subnet. Use VPC Reachability Analyzer to trace the network path.
8. *Available ENI quota.* AWS creates a managed elastic network interface (ENI) in your account for each source subnet and security group combination. Confirm your account has not reached its *Network interfaces per Region* quota, which is enforced per Availability Zone. If your account has reached this quota, AWS cannot create the managed ENI and the check cannot run. For more information, see Amazon VPC quotas.

Reason codes

The describe-application-status response includes a reason for each check. The reason contains the HTTP status code returned by your application (as a number), along with the protocol used for the check. A check is marked `passed` if the returned status code is included in your status code matcher, and `failed` otherwise.

The reason also includes a reason code and, for HTTP-level results, the protocol and the returned HTTP status code. The reason contains the following fields:

Code

The reason code for the application status check result. One of the following values:

- ResponseCodeMatched: the HTTP status code returned by the health check matched the configured StatusCodeMatcher.
- ResponseCodeMismatch: the HTTP status code returned by the health check did not match the configured StatusCodeMatcher.
- ConnectionTimeout: the connection to the target timed out.
- ResponseTimeout: the health check timed out while waiting for a response from the target.
- ConnectionRefused: the target refused the health check connection.
- ConnectionReset: the health check connection was reset before a response was received.

For ResponseCodeMatched and ResponseCodeMismatch, the StatusCode field contains the returned HTTP status code and the Protocol field contains the protocol used for the health check. For connection errors, such as ConnectionTimeout, ResponseTimeout, ConnectionRefused, and ConnectionReset, the StatusCode and Protocol fields are not present.

Protocol

The protocol used for the health check. One of HTTP or HTTPS.

StatusCode

The HTTP status code returned by the health check.

Use the returned HTTP status code to identify why a check failed. Some common examples:

HTTP status code	Typical meaning	Common remediation
200	Application returned a successful response.	None. This is typically a healthy status.
301, 302	Application returned a redirect. Health check calls do not follow redirects.	Point the health check path at the destination of the redirect, or add the redirect code to your status code matcher if you consider it healthy.

HTTP status code	Typical meaning	Common remediation
401, 403	The application requires authentic ation or denied access to the health check path.	Configure the health check path to be unauthenticated, or serve health checks on a path that does not require credentials.
404	The configured health check path was not found on the application.	Confirm the path matches a route your application serves.
500	Application returned an internal server error.	Investigate application logs on the instance.
502, 503, 504	Application is reachable but reports upstream or capacity issues.	Investigate application health, dependencies, and capacity. If your application returns these codes during startup, increase `Initializ ationGracePeriodSeconds` .

For the complete `ApplicationStatusReason` structure, see ApplicationStatusReason in the *Amazon EC2 API Reference*.

Common mistakes

- The security group does not allow inbound traffic from the health check source on the check port.
- The application is bound to `127.0.0.1` and not listening on the network interface.
- The health check path returns a redirect (301, 302) rather than a success response, and the status code matcher does not include the redirect code.
- The check is configured for HTTPS but the application only serves HTTP, or vice versa.
- The application takes longer to start than the `InitializationGracePeriodSeconds` value, and Amazon EC2 Auto Scaling replaces the instance before it is ready.

Monitor application status checks

You can monitor application status checks in three ways:

- **Amazon CloudWatch**. The `StatusCheckFailed_Application` metric reflects the overall application status for the instance and can drive alarms. The metric is aggregated per instance across associated checks whose aggregation setting is `included`. CloudWatch also publishes a per-check metric for each associated check, named `StatusCheckFailed_Application_`*`application-status-check-id`*.
- **describe-instance-status**. Returns the overall application status alongside your instance's other status information.
- **describe-application-status**. Returns detailed per-instance results, including each associated check's individual status and the HTTP status code returned by your application.

Use the CloudWatch metric for alarm-driven automation. Use `describe-instance-status` when you already query it for instance status. Use `describe-application-status` for detailed per-check visibility.

Security and permissions

AWS creates and manages the network interfaces used for application status checks through a service-linked role. No IAM setup is required for the service to create these ENIs. The service-linked role uses the `EC2ApplicationStatusChecksServiceRolePolicy` AWS managed policy.

To create, associate, describe, delete, and suppress application status checks yourself, your IAM user or role needs the corresponding Amazon EC2 permissions. See the *Amazon EC2 API Reference* for the full list of actions.

Your instance's security group must allow inbound traffic from the health check source security group on the port you configured. With AWS managed network paths, AWS provides the source security group; with customer-managed network paths, use the security group you specified as the source.

Pricing

Application status checks are billed on the following components:

- An hourly charge of $0.01 for each managed elastic network interface (ENI), per Availability Zone.
- Standard Amazon CloudWatch pricing applies to application status check metrics.

Quotas

Application status checks are subject to AWS service quotas. For the quota names, default values, and descriptions, see Amazon EC2 endpoints and quotas in the *AWS General Reference*.

In addition to the AWS service quotas that affect the managed network interfaces, application status checks have the following service quotas. You can view your usage and request increases from the Service Quotas console.

In these quotas, a *target* is a single instance that one health check monitors. If more than one health check monitors an instance, each instance and health check pairing counts as a separate target. An *association* is a single tag rule or a single instance ID that you associate with a health check. Each rule or instance ID counts as one association, regardless of how many instances it resolves to.

Quota	Default	Adjustable
Health checks per account	50	Yes, automatically
Associations per health check	50	Yes, automatically
Associations per account	200	Yes, automatically
Targets per account	5,000	Yes, by request

Most quota increases are approved automatically. An increase to *Targets per account* requires a request and manual approval.

> **Important**
>
> If the number of targets in your account exceeds the *Targets per account* quota, the targets over the limit are not monitored and do not report an application status. To avoid gaps in monitoring, keep your target count within the quota or request an increase.

We recommend that you create a Amazon CloudWatch alarm on your application status checks quota usage so that you are notified before you reach a quota. Service Quotas publishes usage metrics to the `AWS/Usage` namespace in CloudWatch, which you can use to create the alarm.

State change events for Amazon EC2 instances

Amazon EC2 sends an `EC2 Instance State-change Notification` event to Amazon EventBridge when the state of an instance changes.

The following is example data for this event. In this example, the instance entered the `pending` state.

```
{
   "id":"7bf73129-1428-4cd3-a780-95db273d1602",
   "detail-type":"EC2 Instance State-change Notification",
   "source":"aws.ec2",
   "account":"123456789012",
   "time":"2021-11-11T21:29:54Z",
   "region":"eusc-de-east-1",
   "resources":[
      "arn:aws-eusc:ec2:eusc-de-east-1:123456789012:instance/i-1234567890abcdef0"
   ],
   "detail":{
      "instance-id":"i-1234567890abcdef0",
      "state":"pending"
   }
}
```

The possible values for `state` are:

- `pending`
- `running`
- `stopping`
- `stopped`
- `shutting-down`
- `terminated`

When you launch or start an instance, it enters the `pending` state and then the `running` state. When you stop an instance, it enters the `stopping` state and then the `stopped` state. When you terminate an instance, it enters the `shutting-down` state and then the `terminated` state. For more information, see Amazon EC2 instance state changes.

Create an alarm that sends an email when an Amazon EC2 instance changes state

To receive email notifications when your instance changes state, create an Amazon SNS topic and then create an EventBridge rule for the `EC2 Instance State-change Notification` event.

To create an SNS topic

1. Open the Amazon SNS console at https://eusc-de-east-1.console.amazonaws-eusc.eu/sns/v3/home.
2. In the navigation pane, choose **Topics**.
3. Choose **Create topic**.
4. For **Type**, choose **Standard**.
5. For **Name**, enter a name for your topic.
6. Choose **Create topic**.
7. Choose **Create subscription**.
8. For **Protocol**, choose **Email**.
9. For **Endpoint**, enter the email address that receives the notifications.
10. Choose **Create subscription**.
11. You'll receive an email message with the following subject line: AWS Notification - Subscription Confirmation. Follow the directions to confirm your subscription.

To create an EventBridge rule

1. Open the Amazon EventBridge console at https://eusc-de-east-1.console.amazonaws-eusc.eu/events/.
2. Choose **Create rule**.
3. For **Name**, enter a name for your rule.
4. For **Rule type**, choose **Rule with an event pattern**.
5. Choose **Next**.
6. For **Event pattern**, do the following:
    a. For **Event source**, choose **AWS services**.
    b. For **AWS service**, choose **EC2**.

c. For **Event type**, choose **EC2 Instance State-change Notification**.

d. By default, we send notifications for any state change for any instance. If you prefer, you can select specific states or specific instances.

7. Choose **Next**.
8. Specify a target as follows:

a. For **Target types**, choose **AWS service**.

b. For **Select a target**, choose **SNS topic**.

c. For **Topic**, choose the SNS topic that you created in the previous procedure.

9. Choose **Next**.
10. (Optional) Add tags to your rule.
11. Choose **Next**.
12. Choose **Create rule**.
13. To test your rule, initiate a state change. For example, start a stopped instance, stop a running instance, or launch an instance. You'll receive email messages with the following subject line: AWS Notification Message. The body of the email contains the event data.

Scheduled events for Amazon EC2 instances

To ensure infrastructure reliability and performance, AWS can schedule events to reboot, stop, and retire your instances. These events do not occur frequently.

If one of your instances will be affected by a scheduled event, AWS notifies you in advance by email, using the email address that's associated with your AWS account. The email provides details about the event, such as the start and end dates. Depending on the event type, you might be able to take action to control the timing of the event. AWS also sends an AWS Health event, which you can monitor and manage by using Amazon EventBridge. For more information, see Monitoring events in AWS Health with Amazon EventBridge.

Scheduled events are managed by AWS. You can't schedule events for your instances. However, you can:

- View scheduled events for your instances.
- Reschedule certain scheduled events.
- Create custom event windows for scheduled events.

- Take action when an instance is scheduled to reboot, stop, or retire.

To ensure that you receive notifications of scheduled events, verify your contact information on the Account page.

> **Note**
>
> When an instance is affected by a scheduled event, and it is part of an Auto Scaling group, Amazon EC2 Auto Scaling eventually replaces it as part of its health checks, with no further action necessary on your part. For more information about the health checks performed by Amazon EC2 Auto Scaling, see Health checks for instances in an Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.

Types of scheduled events

Amazon EC2 can create the following types of scheduled events for your instances, where the event occurs at a scheduled time:

Event type	Event code	Event action
Instance stop	`instance-stop`	At the scheduled time, the instance is stopped. When you start it again, it's migrated to a new host. Applies only to instances with an Amazon EBS root volume.
Instance retirement	`instance-retirement`	At the scheduled time, the instance is stopped if it has an Amazon EBS root volume, or terminated if it has an instance store root volume.
Instance reboot	`instance-reboot`	At the scheduled time, the instance is rebooted. The instance stays on the host, and during the reboot, the

Event type	Event code	Event action
		host undergoes maintenance. This is known as an in-place reboot.
System reboot	`system-reboot`	At the scheduled time, the instance is rebooted and migrated to a new host. This is known as a reboot migration.
System maintenance	`system-maintenance`	At the scheduled time, the instance might be temporarily affected by network maintenance or power maintenance.

Determine the event type

You can check what type of event is scheduled for your instance.

Console

To determine the event type

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Events**.
3. In the table, the event code appears in the **Event type** column.
4. To filter the table to show only the events for instances, in the search field choose **Resource type: instance** from the filter list.

AWS CLI

To determine the event type for an instance

Use the describe-instance-status command. If the instance has an associated scheduled event, the output provides information about the scheduled event.

```
aws ec2 describe-instance-status \
    --instance-ids i-1234567890abcdef0 \
    --query InstanceStatuses[].Events
```

The following is example output. The scheduled event code is `system-reboot`.

```
[
    "Events": [
        {
            "InstanceEventId": "instance-event-0d59937288b749b32",
            "Code": "system-reboot",
            "Description": "The instance is scheduled for a reboot",
            "NotAfter": "2020-03-14T22:00:00.000Z",
            "NotBefore": "2020-03-14T20:00:00.000Z",
            "NotBeforeDeadline": "2020-04-05T11:00:00.000Z"
        }
    ]
]
```

PowerShell

To determine the event type for an instance

Use the Get-EC2InstanceStatus cmdlet. If the instance has an associated scheduled event, the output provides information about the scheduled event.

```
(Get-EC2InstanceStatus `
    -InstanceId i-1234567890abcdef0).Events
```

The following is example output. The scheduled event code is `system-reboot`.

```
Code              : system-reboot
Description       : The instance is scheduled for a reboot
InstanceEventId   : instance-event-0d59937288b749b32
NotAfter          : 2020-03-14T22:00:00.000Z
NotBefore         : 2020-03-14T20:00:00.000Z
NotBeforeDeadline : 2020-04-05T11:00:00.000Z
```

Manage Amazon EC2 instances scheduled to stop or retire

When AWS detects irreparable failure of the underlying host for your instance, it schedules the instance to either stop or terminate, depending on the instance's root volume type.

- If the instance has an Amazon EBS root volume, the instance is scheduled to stop.
- If the instance has an instance store root volume, the instance is scheduled to terminate.

For more information, see Instance retirement.

> **Important**
>
> Any data stored on instance store volumes is lost when an instance is stopped, hibernated, or terminated. This includes instance store volumes that are attached to an instance that has an EBS root volume. Be sure to save data from your instance store volumes that you might need later before the instance is stopped, hibernated, or terminated.

Actions you can take

Actions you can take for instances with an EBS root volume

When you receive a scheduled `instance-stop` event notification, you can take one of the following actions:

- **Wait for scheduled stop:** You can wait for the instance to stop within its scheduled maintenance window.
- **Perform manual stop and start:** You can stop and start the instance yourself at a time that suits you, which migrates it to a new host. This is not the same as rebooting the instance. For more information, see Stop and start Amazon EC2 instances.

- **Automate stop and start:** You can automate an immediate stop and start in response to a scheduled `instance-stop` event. For more information, see Running operations on EC2 instances automatically in response to events in AWS Health in the *AWS Health User Guide*.

Actions you can take for instances with an instance store root volume

When you receive a scheduled `system-retirement` event notification, and you want to retain your data, you can take the following actions:

1. Launch a replacement instance from your most recent AMI.
2. Migrate all necessary data to the replacement instance before the instance is scheduled to terminate.
3. Terminate the original instance, or wait for it to terminate as scheduled.

For more information about the actions you can take, see Instance retirement.

Manage Amazon EC2 instances scheduled for reboot

When AWS must perform tasks such as installing updates or maintaining the underlying host, it can schedule an instance reboot. During the scheduled reboot, the instance either stays on the same host, or migrates to a different host, depending on the event, as follows:

- `instance-reboot` event
  - During the reboot, the instance remains on the host. This is known as an *in-place reboot*.
  - The current host undergoes maintenance.
  - Typically completes in seconds.
- `system-reboot` event
  - During the reboot, the instance is migrated to a new host. This is known as a *reboot migration*.
  - Typically completes in minutes.

To check what type of event is scheduled for your instance, see Determine the event type.

Actions you can take

When you receive a scheduled `instance-reboot` or `system-reboot` event notification, you can take one of the following actions:

- **Wait for scheduled reboot:** You can wait for the instance reboot to occur within its scheduled maintenance window.
- **Reschedule the reboot:** You can reschedule the instance reboot to a date and time that suits you.
- **Perform a user-initiated reboot:** You can manually reboot the instance yourself at a time that suits you. However, the outcome depends on the event:
  - `instance-reboot` event – Your instance remains on the current hardware (in-place reboot), no host maintenance takes place, and the event stays open.
  - `system-reboot` event
    - If reboot migration is enabled on your instance, a user-initiated reboot attempts to migrate your instance to new hardware. If successful, the event is cleared. If unsuccessful, an in-place reboot occurs and the event remains scheduled.
    - If reboot migration is disabled on your instance, a user-initiated reboot keeps the instance on the same hardware (in-place reboot), no host maintenance takes place, and the event remains scheduled. When the scheduled event eventually takes place, AWS will move your instance to new hardware (reboot migration).

After AWS reboots your instance

The following applies after AWS reboots your instance:

- The scheduled event is cleared.
- The event description is updated.
- For an `instance-reboot` event:
  - Maintenance of the underlying host is complete.
- For a `system-reboot` event:
  - The instance moves to a new host.
  - The instance retains its IP address and DNS name.
  - Any data on local instance store volumes is preserved.
- You can use your instance after it has fully booted.

Alternative options

If you can't reschedule the reboot event or enable reboot migration for a user-initiated reboot, but want to maintain normal operation during the scheduled maintenance window, you can do the following:

- **For an instance with an EBS root volume**
  - Manually stop and start the instance to migrate it to a new host. This is not the same as manually rebooting the instance, where the instance stays on the same host.
  - Optionally, automate an immediate instance stop and start in response to the scheduled reboot event. For more information, see Running operations on EC2 instances automatically in response to events in AWS Health in the *AWS Health User Guide*.

  > **Important**
  >
  > The data on instance store volumes is lost when an instance is stopped. For more information, see Stop and start Amazon EC2 instances.

- **For an instance with an instance store root volume**
  1. Launch a replacement instance from your most recent AMI.
  2. Migrate all necessary data to the replacement instance before the scheduled maintenance window.
  3. Terminate the original instance.

Enable or disable reboot migration

When an instance is scheduled for a `system-reboot` event, you can reboot it before the event. The outcome of a user-initiated reboot depends on the instance's reboot migration setting:

- Enabled – A user-initiated reboot attempts to migrate your instance to new hardware (reboot migration). If successful, the event is cleared. If unsuccessful, an in-place reboot occurs and the event remains scheduled. Note that even when enabled, reboot migration can only occur if your instance meets the reboot migration requirements.
- Disabled – A user-initiated reboot keeps the instance on the same hardware (in-place reboot), no host maintenance takes place, and the event remains scheduled. When the scheduled event eventually takes place, AWS will move your instance to new hardware (reboot migration).

A reboot with migration takes longer than an in-place reboot:

- In-place reboot: Approximately 30 seconds
- Reboot with migration: Several minutes

> **Note**
>
> Instances that receive a `system-reboot` event notification are enabled for user-initiated reboot migration by default.

Requirements for enabling reboot migration

Reboot migration can be enabled on instances that meet the following criteria:

Instance types

Not all instance types support enabling reboot migration. You can view the instance types that support enabling reboot migration.

Console

To view the instance types that support enabling reboot migration

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the left navigation pane, choose **Instance Types**.
3. In the filter bar, enter **Reboot Migration support: supported**. As you enter the characters and the filter name appears, you can select it.

   The **Instance types** table displays all the instance types that support enabling reboot migration.

AWS CLI

To view the instance types that support enabling reboot migration

Use the describe-instance-types command with the `reboot-migration-support` filter.

```
aws ec2 describe-instance-types \
```

```
    --filters Name=reboot-migration-support,Values=supported \
    --query "InstanceTypes[*].[InstanceType]" \
    --output text | sort
```

PowerShell

To view the instance types that support enabling reboot migration

Use the Get-EC2InstanceType cmdlet with the `reboot-migration-support` filter.

```
Get-EC2InstanceType `
    -Filter @{Name="reboot-migration-support";Values="true"} | `
    Select InstanceType | Sort-Object InstanceType
```

Tenancy

- Shared
- Dedicated Instance

For more information, see Amazon EC2 Dedicated Instances.

Limitations

Reboot migration is **not** supported for instances with the following characteristics:

- Platform: Instances running natively on the Xen hypervisor
- Instance size: `metal` instances
- Tenancy: Dedicated Host. For Dedicated Hosts, use Dedicated Host Auto Recovery instead.
- Storage: Instances with instance store volumes
- Networking: Instances using an Elastic Fabric Adapter
- Auto Scaling: Instances that are part of an Auto Scaling group

Steps for enabling or disabling reboot migration

When an instance receives a `system-reboot` event, it is enabled for reboot migration by default. You can disable reboot migration so that during a user-initiated reboot, the instance stays on the same hardware (in-place reboot).

The `default` configuration doesn't enable reboot migration for an unsupported instance. For more information, see Requirements for enabling reboot migration.

You can disable or enable reboot migration on a running or stopped instance.

AWS CLI

To disable reboot migration

Use the modify-instance-maintenance-options command and set the `--reboot-migration` parameter to `disabled`.

```
aws ec2 modify-instance-maintenance-options \

    --instance-id i-0abcdef1234567890 \

    --reboot-migration disabled
```

To enable reboot migration

Use the modify-instance-maintenance-options command and set the `--reboot-migration` parameter to `default`.

```
aws ec2 modify-instance-maintenance-options \

    --instance-id i-0abcdef1234567890 \

    --reboot-migration default
```

PowerShell

To disable reboot migration

Use the Edit-EC2InstanceMaintenanceOption cmdlet.

```
Edit-EC2InstanceMaintenanceOption `
    -InstanceId  `
    -RebootMigration Disabled
```

To enable reboot migration

Use the Edit-EC2InstanceMaintenanceOption cmdlet.

```
Edit-EC2InstanceMaintenanceOption `
    -InstanceId i-1234567890abcdef0 `
    -RebootMigration Enabled
```

Manage Amazon EC2 instances scheduled for maintenance

When AWS must maintain the underlying host for an instance, it schedules the instance for maintenance. There are two types of maintenance events: network maintenance and power maintenance.

- During network maintenance, scheduled instances lose network connectivity for a brief period of time. Normal network connectivity to your instance is restored after maintenance is complete.
- During power maintenance, scheduled instances are taken offline for a brief period, and then rebooted. When a reboot is performed, all of your instance's configuration settings are retained.

After your instance has rebooted (this normally takes a few minutes), verify that your application is working as expected. At this point, your instance should no longer have a scheduled event associated with it, or if it does, the description of the scheduled event begins with **[Completed]**. It sometimes takes up to 1 hour for the instance status description to refresh. Completed maintenance events are displayed on the Amazon EC2 console dashboard for up to a week.

Actions you can take

Actions you can take for instances with an EBS root volume

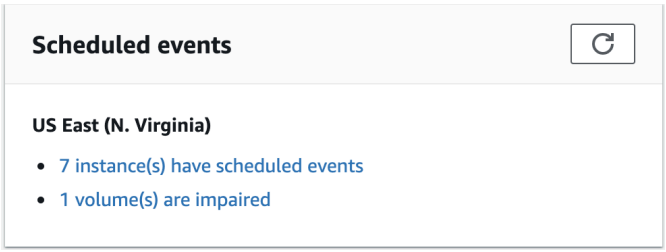
When you receive a `system-maintenance` event notification, you can take one of the following actions:

- **Wait for scheduled maintenance:** You can wait for the maintenance to occur as scheduled.
- **Perform manual stop and stop:** You can stop and start the instance, which migrates it to a new host. This is not the same as rebooting the instance. For more information, see Stop and start Amazon EC2 instances.
- **Automate stop and start:** You can automate an immediate stop and start in response to a scheduled maintenance event. For more information, see Running operations on EC2 instances automatically in response to events in AWS Health in the *AWS Health User Guide*.

Actions you can take for instances with an instance store root volume

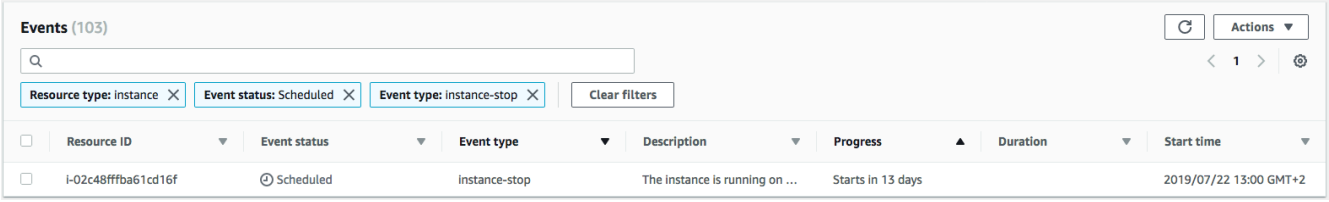
When you receive a `system-maintenance` event notification, you can take one of the following actions:

- **Wait for scheduled maintenance:** You can wait for the maintenance to occur as scheduled.
- **Launch a replacement instance:** If you want to maintain normal operation during the scheduled maintenance window:
  1. Launch a replacement instance from your most recent AMI.
  2. Migrate all necessary data to the replacement instance before the scheduled maintenance window.
  3. Terminate the original instance.



View scheduled events that affect your Amazon EC2 instances

In addition to receiving notification of scheduled events in email, you can check for scheduled events.



Console

To view scheduled events for your instances

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. The dashboard displays any resources with an associated event under **Scheduled events**.

3. For more detail, choose **Events** in the navigation pane. Any resources with an associated event are displayed. You can filter by characteristics such as event type, resource type, and Availability Zone.

AWS CLI

To view scheduled events for your instances

Use the describe-instance-status command.

```
aws ec2 describe-instance-status \
    --instance-ids i-1234567890abcdef0 \
    --query "InstanceStatuses[].Events"
```

The following example output shows a reboot event.

```
[
    "Events": [
        {
            "InstanceEventId": "instance-event-0d59937288b749b32",
            "Code": "system-reboot",
            "Description": "The instance is scheduled for a reboot",
            "NotAfter": "2019-03-15T22:00:00.000Z",
            "NotBefore": "2019-03-14T20:00:00.000Z",
            "NotBeforeDeadline": "2019-04-05T11:00:00.000Z"
         }

    ]
]
```

The following example output shows an instance retirement event.

```
[
    "Events": [
        {
            "InstanceEventId": "instance-event-0e439355b779n26",

            "Code": "instance-stop",
            "Description": "The instance is running on degraded hardware",
            "NotBefore": "2015-05-23T00:00:00.000Z"
        }
    ]
]
```

PowerShell

To view scheduled events for your instances

Use the following Get-EC2InstanceStatus command.

```
(Get-EC2InstanceStatus -InstanceId i-1234567890abcdef0).Events
```

The following example output shows an instance retirement event.

```
Code         : instance-stop
Description  : The instance is running on degraded hardware
NotBefore    : 5/23/2015 12:00:00 AM
```

Instance metadata

To view scheduled events for your instances using instance metadata

You can retrieve information about active maintenance events for your instances from the instance metadata by using Instance Metadata Service Version 2 or Instance Metadata Service Version 1.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/events/maintenance/scheduled
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/events/maintenance/scheduled
```

The following is example output with information about a scheduled system reboot event, in JSON format.

```
[
  {
    "NotBefore" : "21 Jan 2019 09:00:43 GMT",
    "Code" : "system-reboot",
    "Description" : "scheduled reboot",
    "EventId" : "instance-event-0d59937288b749b32",
    "NotAfter" : "21 Jan 2019 09:17:23 GMT",
    "State" : "active"
```

```
  }
]
```

To view event history about completed or canceled events for your instances using instance metadata

You can retrieve information about completed or canceled events for your instances from instance metadata by using Instance Metadata Service Version 2 or Instance Metadata Service Version 1.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/events/maintenance/history
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/events/maintenance/history
```

The following is example output with information about a system reboot event that was canceled, and a system reboot event that was completed, in JSON format.

```
[
  {
    "NotBefore" : "21 Jan 2019 09:00:43 GMT",
    "Code" : "system-reboot",
    "Description" : "[Canceled] scheduled reboot",
    "EventId" : "instance-event-0d59937288b749b32",

AWS Health

You can use the AWS Health Dashboard to learn about events that can affect your instance. The Health Dashboard organizes issues in three groups: open issues, scheduled changes, and other notifications. The scheduled changes group contains items that are ongoing or upcoming.

For more information, see Getting started with your AWS Health Dashboard in the *AWS Health User Guide*.

Reschedule a scheduled event for an EC2 instance

You can reschedule an event so that it occurs at a specific date and time that suits you. After you reschedule an event, it might take a minute or two before the the updated date is displayed.

Limitations

- Only events with an event deadline date can be rescheduled. The event can be rescheduled up to the event deadline date. The event deadline date is indicated in the **Deadline** column (console) and the `NotBeforeDeadline` field (AWS CLI).
- Only events that have not yet started can be rescheduled. The start time is indicated in the **Start time** column (console) and the `NotBefore` field (AWS CLI). Events that are scheduled to start in the next 5 minutes can't be rescheduled.
- The new event start time must be at least 60 minutes from the current time.
- If you reschedule multiple events using the console, the event deadline date is determined by the event with the earliest event deadline date.

Console

To reschedule an event

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Resource type: instance** from the filter list.
4. Select one or more instances, and then choose **Actions**, **Schedule event**.

Only events that have an event deadline date, indicated by a value for **Deadline**, can be rescheduled. If one of the selected events does not have a deadline date, **Actions**, **Schedule event** is disabled.

5. For **New start time**, enter a new date and time for the event. The new date and time must occur before the **Event deadline**.
6. Choose **Save**.

   It might take a minute or two for the updated event start time to be reflected in the console.

AWS CLI

To reschedule an event

Use the modify-instance-event-start-time command.

```
aws ec2 modify-instance-event-start-time \
    --instance-id i-1234567890abcdef0 \
    --instance-event-id instance-event-0d59937288b749b32 \
    --not-before 2020-03-25T10:00:00.000
```

PowerShell

To reschedule an event

Use the Edit-EC2InstanceEventStartTime cmdlet.

```
Edit-EC2InstanceEventStartTime `
    -InstanceId i-1234567890abcdef0 `
    -InstanceEventId instance-event-0d59937288b749b32 `
    -NotBefore 2020-03-25T10:00:00.000
```

Create custom event windows for scheduled events that affect your Amazon EC2 instances

You can define custom event windows that recur weekly for scheduled events that reboot, stop, or terminate your Amazon EC2 instances. You can associate one or more instances with an event

window. If a scheduled event for those instances is planned, AWS will schedule the events within the associated event window.

You can use event windows to maximize workload availability by specifying event windows that occur during off-peak periods for your workload. You can also align the event windows with your internal maintenance schedules.

You define an event window by specifying a set of time ranges. The minimum time range is 2 hours. The combined time ranges must total at least 4 hours.

You can associate one or more instances with an event window by using either instance IDs or instance tags. You can also associate Dedicated Hosts with an event window by using the host ID.

> **Warning**
>
> Event windows are applicable only for scheduled events that stop, reboot, or terminate instances.
> Event windows are not applicable for:
>
> - Expedited scheduled events and network maintenance events.
> - Unscheduled maintenance such as automatic instance recovery and unplanned reboots.

Work with event windows

- Considerations
- Create an event window
- Associate a target with an event window
- Disassociate a target from an event window
- Modify an event window
- Delete an event window

Considerations

- All event window times are in UTC.
- An event window can contain multiple time ranges. While each individual range must be at least 2 hours, the total duration across all ranges must be at least 4 hours.

- Only one target type (instance ID, Dedicated Host ID, or instance tag) can be associated with an event window.
- A target (instance ID, Dedicated Host ID, or instance tag) can only be associated with one event window.
- A maximum of 100 instance IDs, or 50 Dedicated Host IDs, or 50 instance tags can be associated with an event window. The instance tags can be associated with any number of instances.
- A maximum of 200 event windows can be created per AWS Region.
- Multiple instances that are associated with event windows can potentially have scheduled events occur at the same time.
- If AWS has already scheduled an event, modifying an event window won't change the time of the scheduled event. If the event has a deadline date, you can reschedule the event.
- You can stop and start an instance before the scheduled event. This migrates the instance to a new host and clears the event.

Create an event window

You can create one or more event windows. For each event window, you specify one or more blocks of time. For example, you can create an event window with blocks of time that occur every day at 4 AM for 2 hours. Or you can create an event window with blocks of time that occur on Sundays from 2 AM to 4 AM and on Wednesdays from 3 AM to 5 AM.

Event windows recur weekly until you delete them.

Console

To create an event window

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Actions**, **Manage event windows**.
4. Choose **Create instance event window**.
5. For **Event window name**, enter a descriptive name for the event window.
6. For **Event window schedule**, choose to specify the blocks of time in the event window by using the cron schedule builder or by specifying time ranges.
   - If you choose **Cron schedule builder**, specify the following:

1. For **Days (UTC)**, specify the days of the week on which the event window occurs.
2. For **Start time (UTC)**, specify the time when the event window begins.
3. For **Duration**, specify the duration of the blocks of time in the event window. The minimum duration per block of time is 2 hours. The minimum duration of the event window must equal or exceed 4 hours in total. All times are in UTC.

- If you choose **Time ranges**, choose **Add new time range** and specify the start day and time and the end day and time. Repeat for each time range. The minimum duration per time range is 2 hours. The minimum duration for all time ranges combined must equal or exceed 4 hours in total.

7. (Optional) For **Target details**, associate one or more instances with the event window. Use instance IDs or instance tags to associate instances. Use host IDs to associate Dedicated Hosts. When these targets are scheduled for maintenance, the event will occur during this event window.

   Note that you can create the event window without associating a target with the window. Later, you can modify the window to associate one or more targets.
8. (Optional) For **Event window tags**, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.
9. Choose **Create event window**.

AWS CLI

To create an event window with a time range

Use the create-instance-event-window command.

```
aws ec2 create-instance-event-window \
    --time-range StartWeekDay=monday,StartHour=2,EndWeekDay=wednesday,EndHour=8 \
    --tag-specifications "ResourceType=instance-event-
window,Tags=[{Key=K1,Value=V1}]" \
    --name myEventWindowName
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
```

```
        "TimeRanges": [
            {
                "StartWeekDay": "monday",
                "StartHour": 2,
                "EndWeekDay": "wednesday",
                "EndHour": 8
            }
        ],
        "Name": "myEventWindowName",
        "State": "creating",
        "Tags": [
            {
                "Key": "K1",
                "Value": "V1"
            }
        ]
    }
}
```

To create an event window with a cron expression

Use the create-instance-event-window command.

```
aws ec2 create-instance-event-window \
    --cron-expression "* 21-23 * * 2,3" \
    --tag-specifications "ResourceType=instance-event-
window,Tags=[{Key=K1,Value=V1}]" \
    --name myEventWindowName
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "State": "creating",
        "Tags": [
            {
                "Key": "K1",
                "Value": "V1"
            }
        ]
```

```
    }
}
```

PowerShell

To create an event window with a time range

Use the New-EC2InstanceEventWindow cmdlet.

```
$timeRange = New-Object Amazon.EC2.Model.InstanceEventWindowTimeRangeRequest
$timeRange.StartWeekDay = "monday"
$timeRange.EndWeekDay = "wednesday"
$timeRange.StartHour = 2
$timeRange.EndHour = 8
$tag = @{Key="key1"; Value="value1"}
$tagspec = New-Object Amazon.EC2.Model.TagSpecification
$tagspec.ResourceType = "instance-event-window"
$tagspec.Tags.Add($tag)
New-EC2InstanceEventWindow `
    -Name my-event-window `
    -TagSpecification $tagspec `
    -TimeRange @($timeRange)
```

The following is example output.

```
AssociationTarget     :
CronExpression        :
InstanceEventWindowId : iew-0abcdef1234567890
Name                  : my-event-window
State                 : creating
Tags                  : {key1}
TimeRanges            : {Amazon.EC2.Model.InstanceEventWindowTimeRange}
```

To create an event window with a cron expression

Use the New-EC2InstanceEventWindow cmdlet.

```
$tag = @{Key="key1"; Value="value1"}
$tagspec = New-Object Amazon.EC2.Model.TagSpecification
$tagspec.ResourceType = "instance-event-window"
$tagspec.Tags.Add($tag)
New-EC2InstanceEventWindow `
    -Name my-event-window `
```

```
    -TagSpecification $tagspec`
    -CronExpression "* 21-23 * * 2,3"
```

The following is example output.

```
AssociationTarget     :
CronExpression        : * 21-23 * * 2,3
InstanceEventWindowId : iew-0abcdef1234567890
Name                  : my-event-window
State                 : creating
Tags                  : {key1}
TimeRanges            : {}
```

Associate a target with an event window

After you create an event window, you can associate targets with the event window. You can associate only one type of target with an event window. You can specify instance IDs, Dedicated Host IDs, or instance tags.

Console

To associate targets with an event window

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Events**.
3. Select the event window to modify.
4. Choose **Actions**, **Modify instance event window**.

AWS CLI

To associate instance tags with an event window

Use the associate-instance-event-window command.

```
aws ec2 associate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --association-target "InstanceTags=[{Key=k2,Value=v2},{Key=k1,Value=v1}]"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [],
            "Tags": [
                {
                    "Key": "k2",
                    "Value": "v2"
                },
                {
                    "Key": "k1",
                    "Value": "v1"
                }
            ],
            "DedicatedHostIds": []
        },
        "State": "creating"
    }
}
```

To associate instance IDs with an event window

Use the associate-instance-event-window command.

```
aws ec2 associate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --association-target "InstanceIds=i-1234567890abcdef0,i-0598c7d356eba48d7"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [
                "i-1234567890abcdef0",
                "i-0598c7d356eba48d7"
```

```
            ],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating"
    }
}
```

To associate a Dedicated Host with an event window

Use the associate-instance-event-window command.

```
aws ec2 associate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --association-target "DedicatedHostIds=h-029fa35a02b99801d"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [],
            "Tags": [],
            "DedicatedHostIds": [
                "h-029fa35a02b99801d"
            ]
        },
        "State": "creating"
    }
}
```

PowerShell

To associate instance tags with an event window

Use the Register-EC2InstanceEventWindow cmdlet.

```
$tag1 = @{Key="key1"; Value="value1"}
$tag2 = @{Key="key2"; Value="value2"}
```

```
Register-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_InstanceTag @($tag1,$tag2)
```

To associate instance IDs with an event window

Use the Register-EC2InstanceEventWindow cmdlet.

```
Register-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_InstanceId i-1234567890abcdef0, i-0598c7d356eba48d7
```

To associate a Dedicated Host with an event window

Use the Register-EC2InstanceEventWindow cmdlet.

```
Register-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_DedicatedHostId h-029fa35a02b99801d
```

Disassociate a target from an event window

Console

To disassociate targets with an event window

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Events**.
3. Select the event window to modify.
4. Choose **Actions**, **Modify instance event window**.

AWS CLI

To disassociate instance tags from an event window

Use the disassociate-instance-event-window command.

```
aws ec2 disassociate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
```

```
    --association-target "InstanceTags=[{Key=k2,Value=v2},{Key=k1,Value=v1}]"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating"
    }
}
```

To disassociate instance IDs from an event window

Use the disassociate-instance-event-window command.

```
aws ec2 disassociate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --association-target "InstanceIds=i-1234567890abcdef0,i-0598c7d356eba48d7"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating"
    }
}
```

To disassociate a Dedicated Host from an event window

Use the disassociate-instance-event-window command.

```
aws ec2 disassociate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --association-target DedicatedHostIds=h-029fa35a02b99801d
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating"
    }
}
```

PowerShell

To disassociate instance tags from an event window

Use the Unregister-EC2InstanceEventWindow cmdlet.

```
$tag1 = @{Key="key1"; Value="value1"}
$tag2 = @{Key="key2"; Value="value2"}
Unregister-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_InstanceTag @($tag1, $tag2)
```

To disassociate instance IDs from an event window

Use the Unregister-EC2InstanceEventWindow cmdlet.

```
Unregister-EC2InstanceEventWindow `
```

```
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_InstanceId i-1234567890abcdef0, i-0598c7d356eba48d7
```

To disassociate a Dedicated Host from an event window

Use the Unregister-EC2InstanceEventWindow cmdlet.

```
Unregister-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_DedicatedHostId h-029fa35a02b99801d
```

Modify an event window

You can modify all of the fields of an event window except its ID. For example, when daylight savings begin, you might want to modify the event window schedule. For existing event windows, you might want to add or remove targets.

You can modify either a time range or a cron expression when modifying the event window, but not both.

Console

To modify an event window

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Actions**, **Manage event windows**.
4. Select the event window to modify, and then choose **Actions**, **Modify instance event window**.
5. Modify the fields in the event window, and then choose **Modify event window**.

AWS CLI

To modify the time range of an event window

Use the modify-instance-event-window command.

```
aws ec2 modify-instance-event-window
```

```
    --instance-event-window-id iew-0abcdef1234567890 \
    --time-range StartWeekDay=monday,StartHour=2,EndWeekDay=wednesday,EndHour=8
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "TimeRanges": [
            {
                "StartWeekDay": "monday",
                "StartHour": 2,
                "EndWeekDay": "wednesday",
                "EndHour": 8
            }
        ],
        "Name": "myEventWindowName",
        "AssociationTarget": {
            "InstanceIds": [
                "i-0abcdef1234567890",
                "i-0be35f9acb8ba01f0"
            ],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating",
        "Tags": [
            {
                "Key": "K1",
                "Value": "V1"
            }
        ]
    }
}
```

To modify a set of time ranges for an event window

Use the modify-instance-event-window command.

```
aws ec2 modify-instance-event-window
    --instance-event-window-id iew-0abcdef1234567890 \
    --time-range '[{"StartWeekDay": "monday", "StartHour": 2, "EndWeekDay":
 "wednesday", "EndHour": 8},
```

```
   {"StartWeekDay": "thursday", "StartHour": 2, "EndWeekDay": "friday",
 "EndHour": 8}]'
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "TimeRanges": [
            {
                "StartWeekDay": "monday",
                "StartHour": 2,
                "EndWeekDay": "wednesday",
                "EndHour": 8
            },
            {
                "StartWeekDay": "thursday",
                "StartHour": 2,
                "EndWeekDay": "friday",
                "EndHour": 8
            }
        ],
        "Name": "myEventWindowName",
        "AssociationTarget": {
            "InstanceIds": [
                "i-0abcdef1234567890",
                "i-0be35f9acb8ba01f0"
            ],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating",
        "Tags": [
            {
                "Key": "K1",
                "Value": "V1"
            }
        ]
    }
}
```

To modify the cron expression of an event window

Use the modify-instance-event-window command.

```
aws ec2 modify-instance-event-window
    --instance-event-window-id iew-0abcdef1234567890 \
    --cron-expression "* 21-23 * * 2,3"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [
                "i-0abcdef1234567890",
                "i-0be35f9acb8ba01f0"
            ],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating",
        "Tags": [
            {
                "Key": "K1",
                "Value": "V1"
            }
        ]
    }
}
```

PowerShell

To modify the time range of an event window

Use the Edit-EC2InstanceEventWindow cmdlet.

```
$timeRange1 = New-Object Amazon.EC2.Model.InstanceEventWindowTimeRangeRequest
$timeRange1.StartWeekDay = "monday"
$timeRange1.EndWeekDay = "wednesday"
$timeRange1.StartHour = 2
$timeRange1.EndHour = 8
$timeRange2 = New-Object Amazon.EC2.Model.InstanceEventWindowTimeRangeRequest
```

```
$timeRange2.StartWeekDay = "thursday"
$timeRange2.EndWeekDay = "friday"
$timeRange2.StartHour = 1
$timeRange2.EndHour = 6
Edit-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -TimeRange @($timeRange1, $timeRange2)
```

To modify the cron expression of an event window

Use the Edit-EC2InstanceEventWindow cmdlet.

```
Edit-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -CronExpression "* 21-23 * * 2,3"
```

Delete an event window

You can delete one event window at a time.

Console

To delete an event window

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Actions**, **Manage event windows**.
4. Select the event window to delete, and then choose **Actions**, **Delete instance event window**.
5. When prompted, enter **`delete`**, and then choose **Delete**.

AWS CLI

To delete an event window

Use the delete-instance-event-window command and specify the event window to delete.

```
aws ec2 delete-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890
```

To force-delete an event window

Use the `--force-delete` parameter if the event window is currently associated with targets.

```
aws ec2 delete-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --force-delete
```

PowerShell

To delete an event window

Use the Remove-EC2InstanceEventWindow cmdlet.

```
Remove-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890
```

To force-delete an event window

Use the Remove-EC2InstanceEventWindow cmdlet.

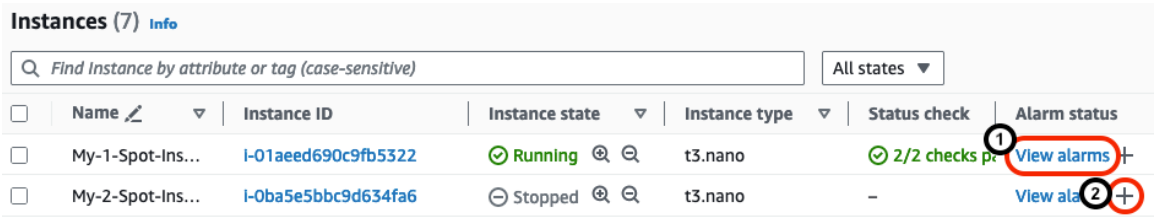
```
Remove-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -ForceDelete $true
```

Monitor your instances using CloudWatch

You can monitor your instances using Amazon CloudWatch, which collects and processes raw data from Amazon EC2 into readable, near real-time metrics. These statistics are recorded for a period of 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing.

By default, Amazon EC2 sends metric data to CloudWatch in 5-minute periods. To send metric data for your instance to CloudWatch in 1-minute periods, you can enable detailed monitoring on the instance. For more information, see Manage detailed monitoring for your EC2 instances.

The Amazon EC2 console displays a series of graphs based on the raw data from Amazon CloudWatch. Depending on your needs, you might prefer to get data for your instances from Amazon CloudWatch instead of the graphs in the console.



For Amazon CloudWatch billing and cost information, see CloudWatch billing and cost in the *Amazon CloudWatch User Guide*.

Contents

- Manage CloudWatch alarms for your EC2 instances in the Amazon EC2 console
- Manage detailed monitoring for your EC2 instances
- CloudWatch metrics that are available for your instances
- Install and configure the CloudWatch agent using the Amazon EC2 console to add additional metrics
- Statistics for CloudWatch metrics for your instances
- View the monitoring graphs for your instances
- Create a CloudWatch alarm for an instance
- Create alarms that stop, terminate, reboot, or recover an instance

Manage CloudWatch alarms for your EC2 instances in the Amazon EC2 console

From the **Instances** screen in the Amazon EC2 console, you can manage the Amazon CloudWatch alarms for your instances. In the **Instances** table, the **Alarm status** column provides two console controls: a control for viewing alarms, and another for creating or editing them. The following screenshot indicates these console controls, numbered **1** (**View alarms**) and **2** (a **+** sign for creating or editing an alarm).

View alarms from the Instances screen

You can view each instance's alarms from the **Instances** screen.

To view an instance's alarm from the Instances screen

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.

2. In the navigation pane, choose **Instances**.
3. In the **Instances** table, for your chosen instance, choose **View alarms** (numbered **1** in the preceding screenshot).
4. In the **Alarm details for *i-1234567890abcdef0*** window, choose the alarm name to view the alarm in the CloudWatch console.

Create alarms from the Instances screen

You can create an alarm for each instance from the **Instances** screen.

To create an alarm for an instance from the Instances screen

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. In the **Instances** table, for your chosen instance, choose the plus sign (numbered **2** in the preceding screenshot).
4. In the **Manage CloudWatch alarms** screen, create your alarm. For more information, see Create a CloudWatch alarm for an instance.

Edit alarms from the Instances screen

You can edit the alarm for an instance from the **Instances** screen.

To edit an alarm for an instance from the Instances screen

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. In the **Instances** table, for your chosen instance, choose the plus sign (numbered **2** in the preceding screenshot).
4. In the **Manage CloudWatch alarms** screen, edit your alarm. For more information, see Edit or delete a CloudWatch alarm in the *Amazon CloudWatch User Guide*.

Manage detailed monitoring for your EC2 instances

Amazon CloudWatch provides two categories of monitoring: *basic monitoring* and *detailed monitoring*. By default, your instance is configured for basic monitoring. You can optionally enable

detailed monitoring to help you more quickly identify and act on operational issues. You can enable or turn off detailed monitoring at launch or when the instance is running or stopped.

Enabling detailed monitoring on an instance does not affect the monitoring of its attached EBS volumes. For more information, see Amazon CloudWatch metrics for Amazon EBS.

The following table highlights the differences between basic monitoring and detailed monitoring for your instances.

Monitoring type	Description	Charges
Basic monitoring	Status check metrics are available in 1-minute periods. All other metrics are available in 5-minute periods.	No charge.
Detailed monitoring	You can get metrics in 1-minute periods, provided you enable detailed monitoring for the instance. After you've enabled detailed monitoring, you can aggregate the data across groups of similar instances.	You are charged per metric that Amazon EC2 sends to CloudWatch. You are not charged for data storage. For more information, see **Paid tier** on the Amazon CloudWatch pricing page.

Contents

- Required permissions
- Enable detailed monitoring at launch
- Manage detailed monitoring

Required permissions

To enable detailed monitoring for an instance, your user must have permission to use the MonitorInstances API action. To turn off detailed monitoring for an instance, your user must have permission to use the UnmonitorInstances API action.

Enable detailed monitoring at launch

Use the following procedures to enable detailed monitoring at launch. By default, your instance uses basic monitoring.

Console

To enable detailed monitoring when launching an instance

When launching an instance using the Amazon EC2 console, under **Advanced details**, select the **Detailed CloudWatch monitoring** checkbox.

AWS CLI

To enable detailed monitoring when launching an instance

Use the run-instances command with the `--monitoring` option.

```
--monitoring Enabled=true
```

PowerShell

To enable detailed monitoring when launching an instance

Use the New-EC2Instance cmdlet with the `-Monitoring` parameter.

```
-Monitoring $true
```

Manage detailed monitoring

Use the following procedures to manage detailed monitoring for a running or stopped instance.

Console

To manage detailed monitoring

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Monitor and troubleshoot**, **Manage detailed monitoring**.
5. On the **Detailed monitoring** page, for **Detailed monitoring**, do one of the following:

- Detailed monitoring – Select **Enable**.
- Basic monitoring – Clear **Enable**.

6. Choose **Confirm**.

AWS CLI

To enable detailed monitoring

Use the following monitor-instances command.

```
aws ec2 monitor-instances --instance-ids i-1234567890abcdef0
```

To disable detailed monitoring

Use the unmonitor-instances command.

```
aws ec2 unmonitor-instances --instance-ids i-1234567890abcdef0
```

PowerShell

To enable detailed monitoring

Use the Start-EC2InstanceMonitoring cmdlet.

```
Start-EC2InstanceMonitoring -InstanceId i-1234567890abcdef0
```

To disable detailed monitoring

Use the Stop-EC2InstanceMonitoring cmdlet.

```
Stop-EC2InstanceMonitoring -InstanceId i-1234567890abcdef0
```

CloudWatch metrics that are available for your instances

Amazon EC2 sends metrics to Amazon CloudWatch. You can use the AWS Management Console, the AWS CLI, or an API to list the metrics that Amazon EC2 sends to CloudWatch. By default, each data point covers the 5 minutes that follow the start time of activity for the instance. If you've enabled detailed monitoring, each data point covers the next minute of activity from the start

time. Note that for the Minimum, Maximum, and Average statistics, the minimum granularity for the metrics that EC2 provides is 1 minute.

For information about how to view the available metrics using the AWS Management Console or the AWS CLI, see View available metrics in the *Amazon CloudWatch User Guide*.

For information about getting the statistics for these metrics, see Statistics for CloudWatch metrics for your instances.

Instance metrics

The `AWS/EC2` namespace includes the following instance metrics.

Metric	Description	Unit	Meaningful statistics
`CPUUtilization`	The percentage of physical CPU time that Amazon EC2 uses to run the EC2 instance, which includes time spent to run both the user code and the Amazon EC2 code. At a very high level, `CPUUtilization` is the sum of guest `CPUUtilization` and hypervisor `CPUUtilization` .	Percent	• Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
	Tools in your operating system can show a different percentage than CloudWatch due to factors such as legacy device simulation, configuration of non-legacy devices, interrupt -heavy workloads, live migration, and live update.		
`DiskReadOps`	Completed read operations from all instance store volumes available to the instance in a specified period of time. To calculate the average I/O operations per second (IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If there are no instance store volumes, either the value is 0 or the metric is not reported.	Count	• Sum • Average • Minimum • Maximum
`DiskWriteOps`	Completed write operations to all instance store volumes available to the instance in a specified period of time. To calculate the average I/O operations per second (IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If there are no instance store volumes, either the value is 0 or the metric is not reported.	Count	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
`DiskReadBytes`	Bytes read from all instance store volumes available to the instance. This metric is used to determine the volume of the data the application reads from the hard disk of the instance. This can be used to determine the speed of the application. The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function `DIFF_TIME` to find the bytes per second. For example, if you have graphed `DiskReadBytes` in CloudWatch as `m1`, the metric math formula `m1/(DIFF_TIME(m1))` returns the metric in bytes/second. For more information about `DIFF_TIME` and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*. If there are no instance store volumes, either the value is 0 or the metric is not reported.	Bytes	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
`DiskWriteBytes`	Bytes written to all instance store volumes available to the instance. This metric is used to determine the volume of the data the application writes onto the hard disk of the instance. This can be used to determine the speed of the application. The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function `DIFF_TIME` to find the bytes per second. For example, if you have graphed `DiskWriteBytes` in CloudWatch as `m1`, the metric math formula `m1/(DIFF_TIME(m1))` returns the metric in bytes/second. For more informati on about `DIFF_TIME` and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*. If there are no instance store volumes, either the value is 0 or the metric is not reported.	Bytes	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
`MetadataNoToken`	The number of times the Instance Metadata Service (IMDS) was successfully accessed using a method that does not use a token. This metric is used to determine if there are any processes accessing instance metadata that are using Instance Metadata Service Version 1 (IMDSv1), which does not use a token. If all requests use token-backed sessions, that is, Instance Metadata Service Version 2 (IMDSv2), the value is 0. For more information, see Transition to using Instance Metadata Service Version 2.	Count	• Sum • Percentiles
`MetadataNoTokenRejected`	The number of times an IMDSv1 call was attempted after IMDSv1 was disabled. If this metric appears, it indicates that an IMDSv1 call was attempted and rejected. You can either re-enable IMDSv1 or make sure all of your calls use IMDSv2. For more informati on, see Transition to using Instance Metadata Service Version 2.	Count	• Sum • Percentiles

Metric	Description	Unit	Meaningful statistics
NetworkIn	The number of bytes received by the instance on all network interfaces. This metric identifies the volume of incoming network traffic to a single instance. The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring and the statistic is Sum, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring and the statistic is Sum, divide it by 60.	Bytes	• Sum • Average • Minimum • Maximum
NetworkOut	The number of bytes sent out by the instance on all network interfaces. This metric identifies the volume of outgoing network traffic from a single instance. The number reported is the number of bytes sent during the period. If you are using basic (5-minute) monitoring and the statistic is Sum, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring and the statistic is Sum, divide it by 60.	Bytes	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
NetworkPackets In	The number of packets received by the instance on all network interfaces. This metric identifies the volume of incoming traffic in terms of the number of packets on a single instance. This metric is available for basic monitoring only (5-minute periods). To calculate the number of packets per second (PPS) your instance received for the 5 minutes, divide the Sum statistic value by 300.	Count	• Sum • Average • Minimum • Maximum
NetworkPackets Out	The number of packets sent out by the instance on all network interfaces. This metric identifies the volume of outgoing traffic in terms of the number of packets on a single instance. This metric is available for basic monitoring only (5-minute periods). To calculate the number of packets per second (PPS) your instance sent for the 5 minutes, divide the Sum statistic value by 300.	Count	• Sum • Average • Minimum • Maximum

Accelerator metrics

The AWS/EC2 namespace includes the following accelerator metric for your accelerated computing instances. Only supported on a subset of accelerated computing instance types.

Metric	Description	Unit	Meaningful statistics
GPUPowerUtilization	Active power usage as a percentage of maximum active power.	Percent	• Average • Minimum • Maximum

CPU credit metrics

The AWS/EC2 namespace includes the following CPU credit metrics for your burstable performance instances.

Metric	Description	Unit	Meaningful statistics
CPUCreditUsage	The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100% utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes). CPU credit metrics are available at a 5-minute frequency only. If you specify a period greater than five minutes, use the Sum statistic instead of the Average statistic.	Credits (vCPU-minutes)	• Sum • Average • Minimum • Maximum
CPUCreditBalance	The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued.	Credits (vCPU-minutes)	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
	Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded . For T2 Standard, launch credits do not count towards the limit. The credits in the `CPUCreditBalance` are available for the instance to spend to burst beyond its baseline CPU utilization. When an instance is running, credits in the `CPUCreditBalance` do not expire. When a T3 or T3a instance stops, the `CPUCreditBalance` value persists for seven days. Thereafter, all accrued credits are lost. When a T2 instance stops, the `CPUCreditBalance` value does not persist, and all accrued credits are lost. CPU credit metrics are available at a 5-minute frequency only.		

Metric	Description	Unit	Meaningful statistics
CPUSurplusCreditBalance	The number of surplus credits that have been spent by an unlimited instance when its CPUCreditBalance value is zero. The CPUSurplusCreditBalance value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the instance can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge. CPU credit metrics are available at a 5-minute frequency only.	Credits (vCPU-minutes)	• Sum • Average • Minimum • Maximum
CPUSurplusCreditsCharged	The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge. Spent surplus credits are charged when any of the following occurs: • The spent surplus credits exceed the maximum number of credits that the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour. • The instance is stopped or terminated. • The instance is switched from unlimited to standard. CPU credit metrics are available at a 5-minute frequency only.	Credits (vCPU-minutes)	• Sum • Average • Minimum • Maximum

Dedicated Host metrics

The AWS/EC2 namespace includes the following metrics for T3 Dedicated Hosts.

Metric	Description	Unit	Meaningful statistics
DedicatedHostCPUUtilization	The percentage of allocated compute capacity that is currently in use by the instances running on the Dedicated Host.	Percent	• Sum • Average • Minimum • Maximum

Amazon EBS metrics for Nitro-based instances

The AWS/EC2 namespace includes additional Amazon EBS metrics for volumes that are attached to Nitro-based instances that are not bare metal instances.

Metric	Description	Unit	Meaningful statistics
InstanceEBSIOPSExceededCheck	Reports whether an application attempted to drive IOPS that exceeds the maximum EBS IOPS limits for the instance within the last minute. This metric can be either 0 (IOPS not exceeded) or 1 (IOPS exceeded).	None	• Sum • Average • Minimum • Maximum
InstanceEBSThroughputExceededCheck	Reports whether an application attempted to drive throughput that exceeds the maximum EBS throughput limits for the instance within the last minute. This metric can be either 0 (throughput not exceeded) or 1 (throughput exceeded).	None	• Sum • Average • Minimum • Maximum
EBSReadOps	Completed read operations from all Amazon EBS volumes attached to the instance in a specified period of time.	Count	• Sum • Average • Minimum

Metric	Description	Unit	Meaningful statistics
	To calculate the average read I/O operations per second (Read IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to calculate the Read IOPS. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function `DIFF_TIME` to find the operations per second. For example, if you have graphed `EBSReadOps` in CloudWatch as `m1`, the metric math formula `m1/(DIFF_TIME(m1))` returns the metric in operations/second. For more information about `DIFF_TIME` and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*.		• Maximum

Metric	Description	Unit	Meaningful statistics
`EBSWriteOps`	Completed write operations to all EBS volumes attached to the instance in a specified period of time. To calculate the average write I/O operations per second (Write IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to calculate the Write IOPS. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function `DIFF_TIME` to find the operations per second. For example, if you have graphed `EBSWriteOps` in CloudWatch as `m1`, the metric math formula `m1/(DIFF_TIME(m1))` returns the metric in operations/second. For more information about `DIFF_TIME` and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*.	Count	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
EBSReadBytes	Bytes read from all EBS volumes attached to the instance in a specified period of time. The number reported is the number of bytes read during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Read Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function DIFF_TIME to find the bytes per second. For example, if you have graphed EBSReadBytes in CloudWatch as m1, the metric math formula m1/(DIFF_TIME(m1)) returns the metric in bytes/second. For more information about DIFF_TIME and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*.	Bytes	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
EBSWriteBytes	Bytes written to all EBS volumes attached to the instance in a specified period of time. The number reported is the number of bytes written during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Write Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function DIFF_TIME to find the bytes per second. For example, if you have graphed EBSWriteBytes in CloudWatch as m1, the metric math formula m1/(DIFF_TIME(m1)) returns the metric in bytes/second. For more information about DIFF_TIME and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*.	Bytes	• Sum • Average • Minimum • Maximum
EBSIOBalance%	Provides information about the percentage of I/O credits remaining in the burst bucket. This metric is available for basic monitoring only. This metric is available only for some *.4xlarge instance sizes and smaller that burst to their maximum performance for only 30 minutes at least once every 24 hours. The Sum statistic is not applicable to this metric.	Percent	• Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
EBSByteBalance%	Provides information about the percentage of throughput credits remaining in the burst bucket. This metric is available for basic monitoring only. This metric is available only for some *.4xlarge instance sizes and smaller that burst to their maximum performance for only 30 minutes at least once every 24 hours. The Sum statistic is not applicable to this metric.	Percent	• Minimum • Maximum

For information about the metrics provided for your EBS volumes, see Metrics for Amazon EBS volumes in the *Amazon EBS User Guide*. For information about the metrics provided for your EC2 Fleets and Spot Fleets, see Monitor your EC2 Fleet or Spot Fleet using CloudWatch.

Status check metrics

By default, status check metrics are available at a 1-minute frequency at no charge. For a newly-launched instance, status check metric data is only available after the instance has completed the initialization state (within a few minutes of the instance entering the running state). For more information about EC2 status checks, see Status checks for Amazon EC2 instances.

The AWS/EC2 namespace includes the following status check metrics.

Metric	Description	Unit	Meaningful statistics
StatusCheckFailed	Reports whether the instance has passed all status checks in the last minute. This metric can be either 0 (passed) or 1 (failed).	Count	• Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
	By default, this metric is available at a 1-minute frequency at no charge.		
StatusCheckFailed_Instance	Reports whether the instance has passed the instance status check in the last minute. This metric can be either 0 (passed) or 1 (failed). By default, this metric is available at a 1-minute frequency at no charge.	Count	• Average • Minimum • Maximum
StatusCheckFailed_System	Reports whether the instance has passed the system status check in the last minute. This metric can be either 0 (passed) or 1 (failed). By default, this metric is available at a 1-minute frequency at no charge.	Count	• Average • Minimum • Maximum
StatusCheckFailed_AttachedEBS	Reports whether the instance has passed the attached EBS status check in the last minute. This metric can be either 0 (passed) or 1 (failed). By default, this metric is available at a 1-minute frequency at no charge.	Count	• Average • Minimum • Maximum

The AWS/EBS namespace includes the following status check metric.

Metric	Description	Unit	Meaningful statistics
VolumeStalledIOCheck	**Note:** For Nitro instances only. Not published for volumes attached to Amazon ECS and AWS Fargate tasks. Reports whether a volume has passed or failed a *stalled IO check* in the last minute. This metric can be either 0 (passed) or 1 (failed).	None	• Average • Minimum • Maximum

Traffic mirroring metrics

The AWS/EC2 namespace includes metrics for mirrored traffic. For more information, see Monitor mirrored traffic using Amazon CloudWatch in the *Amazon VPC Traffic Mirroring Guide*.

Auto Scaling group metrics

The AWS/AutoScaling namespace includes metrics for Auto Scaling groups. For more information, see Monitor CloudWatch metrics for your Auto Scaling groups and instances in the *Amazon EC2 Auto Scaling User Guide*.

Amazon EC2 metric dimensions

You can use the following dimensions to refine the metrics listed in the previous tables.

Dimension	Description
AutoScalingGroupName	This dimension filters the data you request for all instances in a specified capacity group. An *Auto Scaling group* is a collection of instances you define if you're using Auto Scaling. This dimension is available only for Amazon EC2 metrics when the instances are in such an Auto Scaling group. Available for instances with Detailed or Basic Monitoring enabled.
ImageId	This dimension filters the data you request for all instances running this Amazon EC2 Amazon Machine Image (AMI). Available for instances with Detailed Monitoring enabled.

Dimension	Description
`InstanceId`	This dimension filters the data you request for the identified instance only. This helps you pinpoint an exact instance from which to monitor data.
`InstanceType`	This dimension filters the data you request for all instances running with this specified instance type. This helps you categorize your data by the type of instance running. For example, you might compare data from an m1.small instance and an m1.large instance to determine which has the better business value for your application. Available for instances with Detailed Monitoring enabled.

Amazon EC2 usage metrics

You can use CloudWatch usage metrics to provide visibility into your account's usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

Amazon EC2 usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about CloudWatch integration with service quotas, see AWS usage metrics in the *Amazon CloudWatch User Guide*.

Amazon EC2 publishes the following metrics in the `AWS/Usage` namespace.

Metric	Description
`ResourceCount`	The number of the specified resources running in your account. The resources are defined by the dimensions associated with the metric. The most useful statistic for this metric is `MAXIMUM`, which represents the maximum number of resources used during the 1-minute period.

The following dimensions are used to refine the usage metrics that are published by Amazon EC2.

Dimension	Description
Service	The name of the AWS service containing the resource. For Amazon EC2 usage metrics, the value for this dimension is EC2.
Type	The type of entity that is being reported. Currently, the only valid value for Amazon EC2 usage metrics is Resource.
Resource	The type of resource that is running. Currently, the only valid value for Amazon EC2 usage metrics is vCPU, which returns information on instances that are running.
Class	The class of resource being tracked. For Amazon EC2 usage metrics with vCPU as the value of the Resource dimension, the valid values are Standard/OnDemand , F/OnDemand , G/OnDemand , Inf/OnDemand , P/OnDemand , and X/OnDemand . The values for this dimension define the first letter of the instance types that are reported by the metric. For example, Standard/OnDemand returns information about all running instances with types that start with A, C, D, H, I, M, R, T, and Z, and G/OnDemand returns information about all running instances with types that start with G.

Install and configure the CloudWatch agent using the Amazon EC2 console to add additional metrics

Description
Installing and configuring the CloudWatch agent using the Amazon EC2 console is in beta for Amazon EC2 and is subject to change.

By default, Amazon CloudWatch provides basic metrics, such as CPUUtilization and NetworkIn, for monitoring your Amazon EC2 instances. To collect additional metrics, you can

install the CloudWatch agent on your EC2 instances, and then configure the agent to emit selected metrics. Instead of manually installing and configuring the CloudWatch agent on every EC2 instance, you can use the Amazon EC2 console to do this for you.

You can use the Amazon EC2 console to install the CloudWatch agent on your instances and configure the agent to emit selected metrics.

Alternatively, to complete this process manually, see Installing the CloudWatch agent in the *Amazon CloudWatch User Guide*. For more information about the CloudWatch agent, see Collect metrics, logs, and traces using the CloudWatch agent.

Contents

- Prerequisites
- How it works
- Costs
- Install and configure the CloudWatch agent

Prerequisites

To use Amazon EC2 to install and configure the CloudWatch agent, you must meet the user and instance prerequisites described in this section.

> **Tip**
>
> This feature is not available in all AWS Regions. If the menu item described in the installation procedure on this page does not exist in the Amazon EC2 console and you are flexible about where your instances run, try another Region. Otherwise, you can use the manual directions in the *Amazon CloudWatch User Guide* to install and configure the agent.

User prerequisites

To use this feature, your IAM console user or role must have the permissions required for using Amazon EC2 and the following IAM permissions:

JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetParameter",
                "ssm:PutParameter"
            ],
            "Resource": "arn:aws-eusc:ssm:*:*:parameter/EC2-Custom-Metrics-*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:SendCommand",
                "ssm:ListCommandInvocations",
                "ssm:DescribeInstanceInformation"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:GetInstanceProfile",
                "iam:SimulatePrincipalPolicy"
            ],
            "Resource": "*"
        }
    ]
}
```

Instance prerequisites

- Instance state: `running`
- Supported operating system: Linux
- AWS Systems Manager Agent (SSM Agent): Installed. Two notes about SSM Agent:
  - SSM Agent is preinstalled on some Amazon Machine Images (AMIs) provided by AWS and trusted third-parties. For information about the supported AMIs and the instructions for installing SSM Agent, see Amazon Machine Images (AMIs) with SSM Agent preinstalled in the *AWS Systems Manager User Guide*.

- If you experience issues with the SSM Agent, see Troubleshooting SSM Agent in the *AWS Systems Manager User Guide*.

- IAM permissions for the instance: The following AWS managed policies must be added to an IAM role that is attached to the instance:
  - AmazonSSMManagedInstanceCore – Enables an instance to use Systems Manager to install and configure the CloudWatch agent.
  - CloudWatchAgentServerPolicy – Enables an instance to use the CloudWatch agent to write data to CloudWatch.

  For information about how to add IAM permissions to your instance, see Use instance profiles in the *IAM User Guide*.

How it works

Before you can use the Amazon EC2 console to install and configure the CloudWatch agent, you must make sure that your IAM user or role, and the instances on which you want to add metrics, meet certain prerequisites. Then, you can use the Amazon EC2 console to install and configure the CloudWatch agent on your selected instances.

First meet the prerequisites

- **You need the required IAM permissions** – Before you get started, make sure that your console user or role has the required IAM permissions to use this feature.
- **Instances** – To use the feature, your EC2 instances must be Linux instances, have the SSM Agent installed, have the required IAM permissions, and be running.

Then you can use the feature

1. **Select your instances** – In the Amazon EC2 console, you select the instances on which to install and configure the CloudWatch agent. You then start the process by choosing **Configure CloudWatch agent**.
2. **Validate SSM Agent** – Amazon EC2 checks that the SSM Agent is installed and started on each instance. Any instances that fail this check are excluded from the process. The SSM Agent is used for performing actions on the instance during this process.
3. **Validate IAM permissions** – Amazon EC2 checks that each instance has the required IAM permissions for this process. Any instances that fail this check are excluded from the process.

The IAM permissions enable the CloudWatch agent to collect metrics from the instance and integrate with AWS Systems Manager to use the SSM Agent.

4. **Validate CloudWatch agent** – Amazon EC2 checks that the CloudWatch agent is installed and running on each instance. If any instances fail this check, Amazon EC2 offers to install and start the CloudWatch agent for you. The CloudWatch agent will collect the selected metrics on each instance after this process is completed.
5. **Select metric configuration** – You select the metrics for the CloudWatch agent to emit from your instances. Once selected, Amazon EC2 stores a configuration file in Parameter Store, where it remains until the process is completed. Amazon EC2 will delete the configuration file from Parameter Store unless the process is interrupted. Note that if you don't select a metric, but you previously added it to your instance, it will be removed from your instance when this process is completed.
6. **Update CloudWatch agent configuration** – Amazon EC2 sends the metric configuration to the CloudWatch agent. This is the last step in the process. If it succeeds, your instances can emit data for the selected metrics and Amazon EC2 deletes the configuration file from Parameter Store.

Costs

Additional metrics that you add during this process are billed as custom metrics. For more information about CloudWatch metrics pricing, see Amazon CloudWatch Pricing.

Install and configure the CloudWatch agent

You can use the Amazon EC2 console to install and configure the CloudWatch agent to add additional metrics.

> **Note**
>
> Every time you perform this procedure, you overwrite the existing CloudWatch agent configuration. If you don't select a metric that was selected previously, it will be removed from the instance.

To install and configure the CloudWatch agent using the Amazon EC2 console

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.

3. Select the instances on which to install and configure the CloudWatch agent.
4. Choose **Actions**, **Monitor and troubleshoot**, **Configure CloudWatch agent**.
5. For each step in the process, read the console text, and then choose **Next**.
6. To complete the process, in the final step, choose **Complete**.

To update the agent configuration created by the Amazon EC2 console

You can manually customize the configuration that the EC2 console created. For more information, see Manually create or edit the CloudWatch agent configuration file in the *Amazon CloudWatch User Guide*.

Statistics for CloudWatch metrics for your instances

You can get statistics for the CloudWatch metrics for your instances. *Statistics* are metric data aggregations over specified periods of time. CloudWatch provides statistics based on the metric data points provided by your custom data or provided by other services in AWS to CloudWatch. Aggregations are made using the namespace, metric name, dimensions, and the data point unit of measure, within the time period you specify. The following table describes the available statistics.

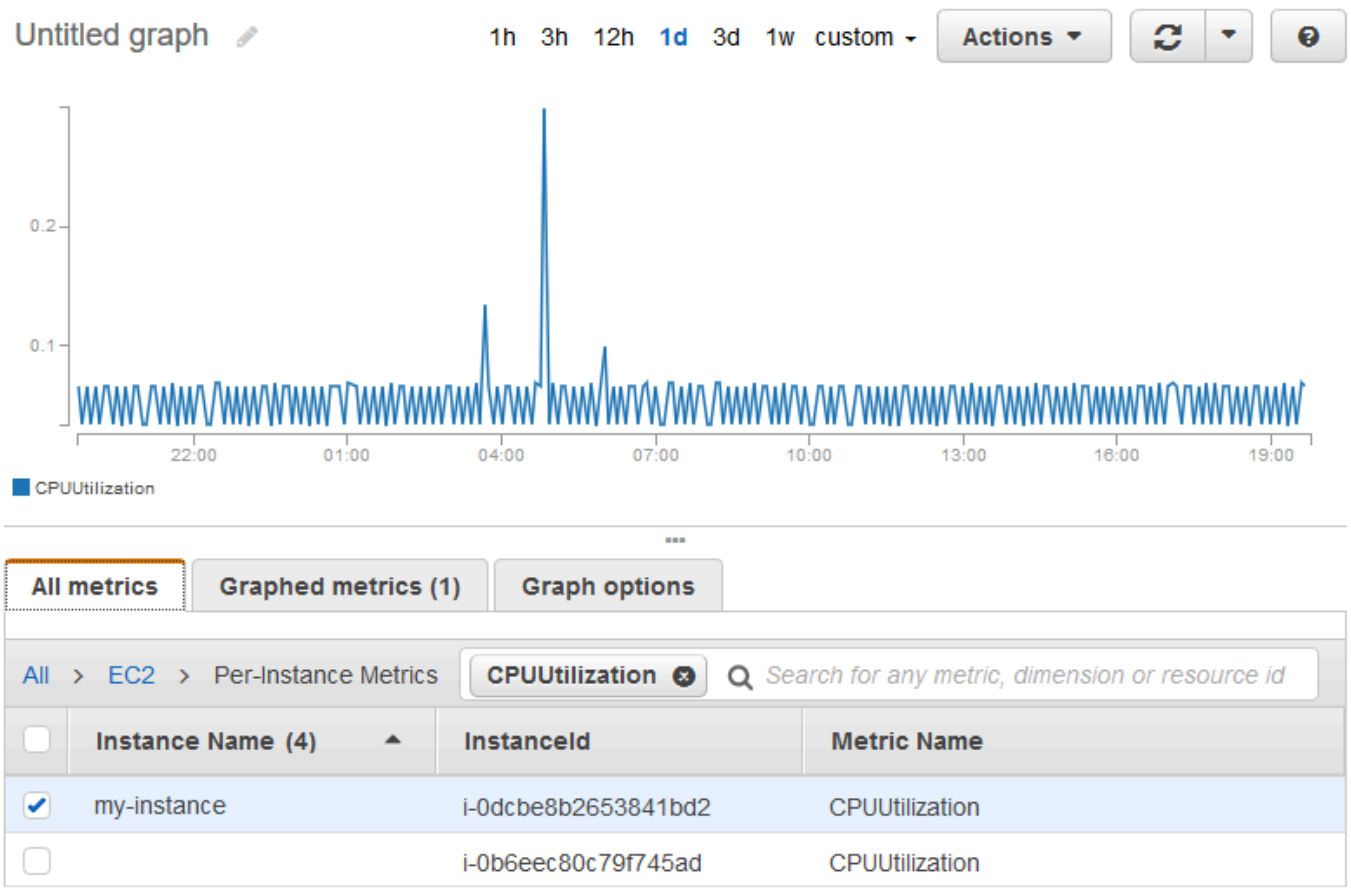
Statistic	Description
`Minimum`	The lowest value observed during the specified period. You can use this value to determine low volumes of activity for your application.
`Maximum`	The highest value observed during the specified period. You can use this value to determine high volumes of activity for your application.
`Sum`	All values submitted for the matching metric added together. This statistic can be useful for determining the total volume of a metric.
`Average`	The value of `Sum` / `SampleCount` during the specified period. By comparing this statistic with the `Minimum` and `Maximum`, you can determine the full scope of a metric and how close the average use is to the `Minimum` and `Maximum`. This comparison helps you to know when to increase or decrease your resources as needed.
`SampleCount`	The count (number) of data points used for the statistical calculation.

Statistic	Description
pNN.NN	The value of the specified percentile. You can specify any percentile, using up to two decimal places (for example, p95.45).

Contents

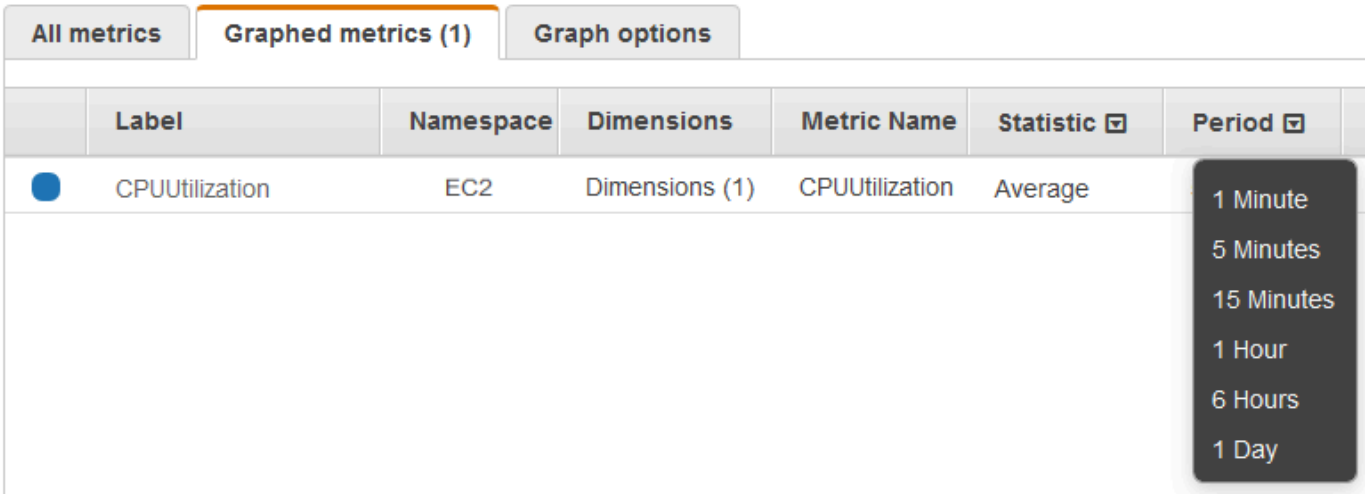
- Get statistics for a specific instance
- Aggregate statistics across instances
- Aggregate statistics by Auto Scaling group
- Aggregate statistics by AMI

Get statistics for a specific instance



You can use the AWS Management Console or the AWS CLI to get statistics for a specific instance. The following examples show you how to use the AWS Management Console or the AWS CLI to determine the maximum CPU utilization of a specific EC2 instance.

Requirements



- You must have the ID of the instance. You can get the instance ID using the AWS Management Console or the describe-instances command.
- By default, basic monitoring is enabled, but you can enable detailed monitoring. For more information, see Manage detailed monitoring for your EC2 instances.

To display the CPU utilization for a specific instance (console)

1. Open the CloudWatch console at https://eusc-de-east-1.console.amazonaws-eusc.eu/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the **EC2** metric namespace.
4. Choose the **Per-Instance Metrics** dimension.
5. In the search field, enter **`CPUUtilization`** and press Enter. Choose the row for the specific instance, which displays a graph for the **CPUUtilization** metric for the instance. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.

6. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

To get the CPU utilization for a specific instance (AWS CLI)

Use the following get-metric-statistics command to get the **CPUUtilization** metric for the specified instance, using the specified period and time interval:

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization
 --period 3600 \
--statistics Maximum --dimensions Name=InstanceId,Value=i-1234567890abcdef0 \
--start-time 2022-10-18T23:18:00 --end-time 2022-10-19T23:18:00
```

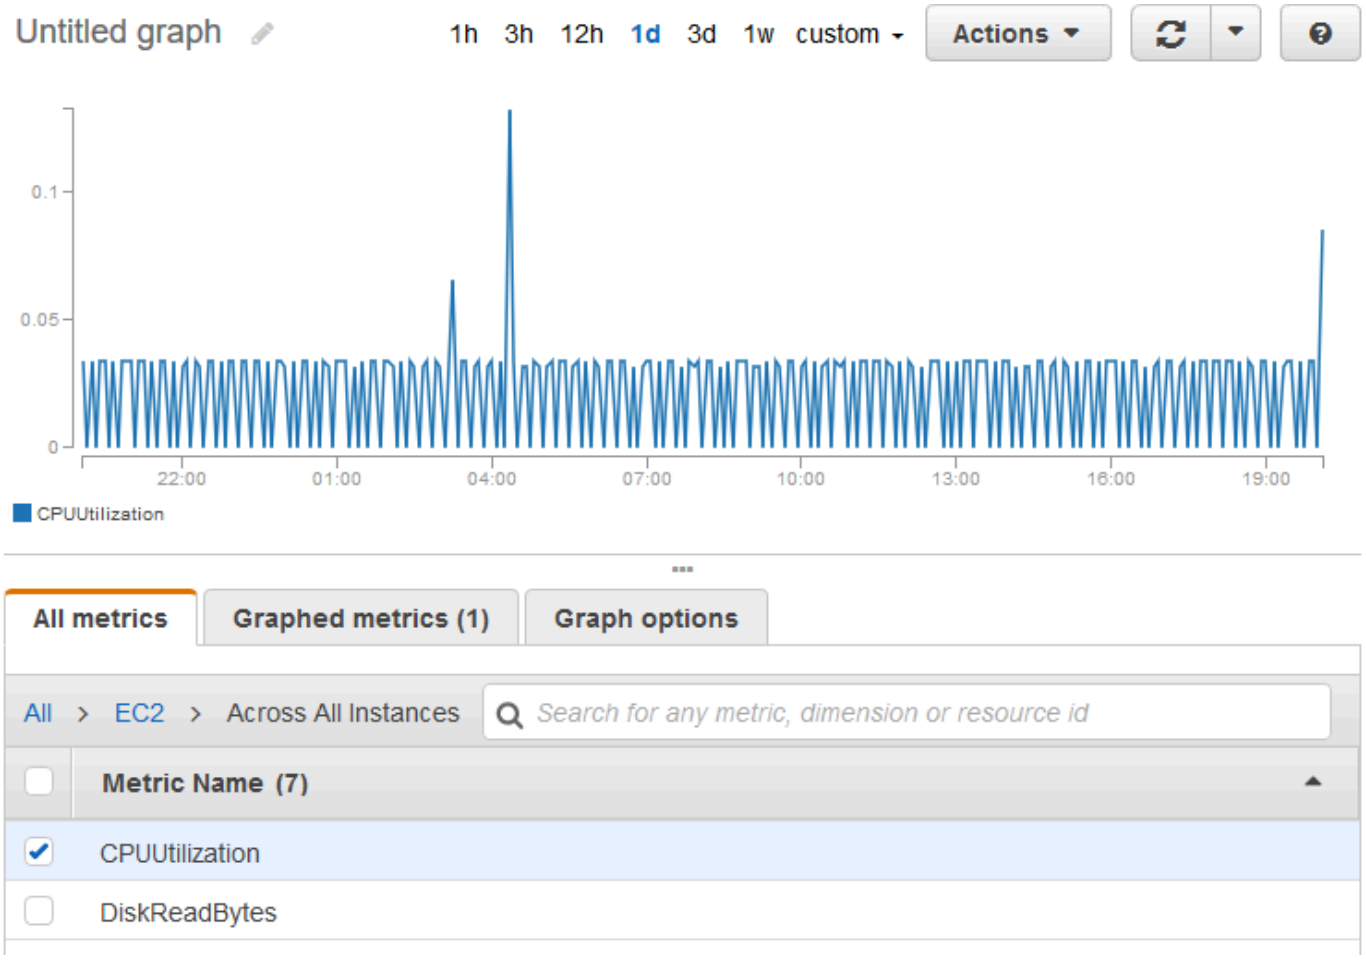
The following is example output. Each value represents the maximum CPU utilization percentage for a single EC2 instance.

```
{
    "Datapoints": [
        {
            "Timestamp": "2022-10-19T00:18:00Z",
            "Maximum": 0.33000000000000002,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2022-10-19T03:18:00Z",
            "Maximum": 99.670000000000002,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2022-10-19T07:18:00Z",
            "Maximum": 0.34000000000000002,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2022-10-19T12:18:00Z",
            "Maximum": 0.34000000000000002,
            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```

Aggregate statistics across instances

Aggregate statistics are available for instances that have detailed monitoring enabled. Instances that use basic monitoring are not included in the aggregates. Before you can get statistics

aggregated across instances, you must enable detailed monitoring (at an additional charge), which provides data in 1-minute periods.



Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to use detailed monitoring to get the average CPU usage for your EC2 instances. Because no dimension is specified, CloudWatch returns statistics for all dimensions in the `AWS/EC2` namespace.

> **Important**
>
> This technique for retrieving all dimensions across an AWS namespace does not work for custom namespaces that you publish to Amazon CloudWatch. With custom namespaces, you must specify the complete set of dimensions that are associated with any given data point to retrieve statistics that include the data point.

To display average CPU utilization across your instances (console)

1. Open the CloudWatch console at https://eusc-de-east-1.console.amazonaws-eusc.eu/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the **EC2** namespace and then choose **Across All Instances**.
4. Choose the row that contains **CPUUtilization**, which displays a graph for the metric for all your EC2 instances. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.

5. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

To get average CPU utilization across your instances (AWS CLI)

Use the get-metric-statistics command as follows to get the average of the **CPUUtilization** metric across your instances.

```
aws cloudwatch get-metric-statistics \
    --namespace AWS/EC2 \
    --metric-name CPUUtilization \
    --period 3600  --statistics "Average" "SampleCount" \
    --start-time 2022-10-11T23:18:00 \
    --end-time 2022-10-12T23:18:00
```

The following is example output:

```
{
    "Datapoints": [
        {
            "SampleCount": 238.0,
            "Timestamp": "2022-10-12T07:18:00Z",
            "Average": 0.038235294117647062,
            "Unit": "Percent"
        },
        {
            "SampleCount": 240.0,
            "Timestamp": "2022-10-12T09:18:00Z",
            "Average": 0.16670833333333332,
            "Unit": "Percent"
        },
        {
            "SampleCount": 238.0,
            "Timestamp": "2022-10-11T23:18:00Z",
            "Average": 0.041596638655462197,
            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```

Aggregate statistics by Auto Scaling group

You can aggregate statistics for the EC2 instances in an Auto Scaling group. Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to retrieve the total bytes written to disk for one Auto Scaling group. The total is computed for 1-minute periods for a 24-hour interval across all EC2 instances in the specified Auto Scaling group.

To display DiskWriteBytes for the instances in an Auto Scaling group (console)

1. Open the CloudWatch console at https://eusc-de-east-1.console.amazonaws-eusc.eu/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the **EC2** namespace and then choose **By Auto Scaling Group**.

4. Choose the row for the **DiskWriteBytes** metric and the specific Auto Scaling group, which displays a graph for the metric for the instances in the Auto Scaling group. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.
5. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

To display DiskWriteBytes for the instances in an Auto Scaling group (AWS CLI)

Use the get-metric-statistics command as follows.

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name DiskWriteBytes
 --period 360 \
--statistics "Sum" "SampleCount" --dimensions Name=AutoScalingGroupName,Value=my-asg --
start-time 2022-10-16T23:18:00 --end-time 2022-10-18T23:18:00
```

The following is example output:

```
{
    "Datapoints": [
        {
            "SampleCount": 18.0,
            "Timestamp": "2022-10-19T21:36:00Z",
            "Sum": 0.0,
            "Unit": "Bytes"
        },
        {
            "SampleCount": 5.0,
            "Timestamp": "2022-10-19T21:42:00Z",
            "Sum": 0.0,
            "Unit": "Bytes"
        }
    ],
    "Label": "DiskWriteBytes"
}
```

Aggregate statistics by AMI

You can aggregate statistics by AMI for your instances that have detailed monitoring enabled. Instances that use basic monitoring are not included in the aggregates. Before you can get

statistics aggregated across instances, you must enable detailed monitoring (at an additional charge), which provides data in 1-minute periods.

Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to determine average CPU utilization for all instances that use a specific Amazon Machine Image (AMI). The average is over 60-second time intervals for a one-day period.

To display the average CPU utilization by AMI (console)

1. Open the CloudWatch console at https://eusc-de-east-1.console.amazonaws-eusc.eu/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the **EC2** namespace and then choose **By Image (AMI) Id**.
4. Choose the row for the **CPUUtilization** metric and the specific AMI, which displays a graph for the metric for the specified AMI. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.
5. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

To get the average CPU utilization for an image ID (AWS CLI)

Use the get-metric-statistics command as follows.

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization
 --period 3600 \
--statistics Average --dimensions Name=ImageId,Value=ami-3c47a355 --start-
time 2022-10-10T00:00:00 --end-time 2022-10-11T00:00:00
```

The following is example output. Each value represents an average CPU utilization percentage for the EC2 instances running the specified AMI.

```
{
    "Datapoints": [
        {
            "Timestamp": "2022-10-10T07:00:00Z",
```

```
            "Average": 0.041000000000000009,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2022-10-10T14:00:00Z",
            "Average": 0.079579831932773085,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2022-10-10T06:00:00Z",
            "Average": 0.036000000000000011,
            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```

View the monitoring graphs for your instances

After you launch an instance, you can open the Amazon EC2 console and view the monitoring graphs for the instance on the **Monitoring** tab. Each graph is based on one of the available Amazon EC2 metrics.

The following graphs are available:

- Average CPU Utilization (Percent)
- Average Disk Reads (Bytes)
- Average Disk Writes (Bytes)
- Maximum Network In (Bytes)
- Maximum Network Out (Bytes)
- Summary Disk Read Operations (Count)
- Summary Disk Write Operations (Count)
- Summary Status (Any)
- Summary Status Instance (Count)
- Summary Status System (Count)

For more information about the metrics and the data they provide to the graphs, see CloudWatch metrics that are available for your instances.

Graph metrics using the CloudWatch console

You can also use the CloudWatch console to graph metric data generated by Amazon EC2 and other AWS services. For more information, see Graphing metrics in the *Amazon CloudWatch User Guide*.

Create a CloudWatch alarm for an instance

You can create a CloudWatch alarm that monitors CloudWatch metrics for one of your instances. CloudWatch will automatically send you a notification when the metric reaches a threshold you specify. You can create a CloudWatch alarm using the Amazon EC2 console, or using the more advanced options provided by the CloudWatch console.

To create an alarm using the CloudWatch console

For examples, see Creating Amazon CloudWatch Alarms in the *Amazon CloudWatch User Guide*.

To create an alarm using the Amazon EC2 console

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **Manage CloudWatch alarms**.
4. On the **Manage CloudWatch alarms** detail page, under **Add or edit alarm**, select **Create an alarm**.
5. For **Alarm notification**, choose whether to configure Amazon Simple Notification Service (Amazon SNS) notifications. Enter an existing Amazon SNS topic or enter a name to create a new topic.
6. For **Alarm action**, choose whether to specify an action to take when the alarm is triggered. Choose an action from the list.
7. For **Alarm thresholds**, select the metric and criteria for the alarm. For example, to create an alarm that is triggered when CPU utilization reaches 80% for a 5 minute period, do the following:

    a. Keep the default setting for **Group samples by** (**Average**) and **Type of data to sample** (**CPU utilization**).

    b. Choose **>=** for **Alarm when** and enter **`0.80`** for **Percent**.

    c. Enter **1** for **Consecutive period** and select **5 minutes** for **Period**.

8. (Optional) For **Sample metric data**, choose **Add to dashboard**.
9. Choose **Create**.

You can edit your CloudWatch alarm settings from the Amazon EC2 console or the CloudWatch console. If you want to delete your alarm, you can do so from the CloudWatch console. For more information, see Edit or delete a CloudWatch alarm in the *Amazon CloudWatch User Guide*.

Create alarms that stop, terminate, reboot, or recover an instance

Using Amazon CloudWatch alarm actions, you can create alarms that automatically stop, terminate, reboot, or recover your instances. You can use the stop or terminate actions to help you save money when you no longer need an instance to be running. You can use the reboot and recover actions to automatically reboot those instances or recover them onto new hardware if a system impairment occurs.

> **Note**
>
> For Amazon CloudWatch alarms billing and pricing information, see CloudWatch billing and cost in the *Amazon CloudWatch User Guide*.

The `AWSServiceRoleForCloudWatchEvents` service-linked role enables AWS to perform alarm actions on your behalf. The first time you create an alarm in the AWS Management Console, the AWS CLI, or the IAM API, CloudWatch creates the service-linked role for you.

There are a number of scenarios in which you might want to automatically stop or terminate your instance. For example, you might have instances dedicated to batch payroll processing jobs or scientific computing tasks that run for a period of time and then complete their work. Rather than letting those instances sit idle (and accrue charges), you can stop or terminate them, which can help you to save money. The main difference between using the stop and the terminate alarm actions is that you can easily start a stopped instance if you need to run it again later, and you can keep the same instance ID and root volume. However, you cannot start a terminated instance. Instead, you must launch a new instance. When an instance is stopped or terminated, data on instance store volumes is lost.

You can add the stop, terminate, reboot, or recover actions to any alarm that is set on an Amazon EC2 per-instance metric, including basic and detailed monitoring metrics provided by Amazon

CloudWatch (in the AWS/EC2 namespace), as well as any custom metrics that include the InstanceId dimension, as long as its value refers to a valid running Amazon EC2 instance.

> **Important**
>
> Status check alarms can temporarily enter the INSUFFICIENT_DATA state if there are missing metric data points. Although rare, this can happen when there is an interruption in the metric reporting systems, even when an instance is healthy. We recommend that you treat the INSUFFICIENT_DATA state as missing data instead of an alarm breach, especially when configuring the alarm to stop, terminate, reboot, or recover an instance.

Console support

You can create alarms using the Amazon EC2 console or the CloudWatch console. The procedures in this documentation use the Amazon EC2 console. For procedures that use the CloudWatch console, see Create alarms that stop, terminate, reboot, or recover an instance in the *Amazon CloudWatch User Guide*.

Permissions

You must have the iam:CreateServiceLinkedRole to create or modify an alarm that performs EC2 alarm actions. A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an AWS service in the *IAM User Guide*.

Contents

- Add stop actions to Amazon CloudWatch alarms
- Add terminate actions to Amazon CloudWatch alarms
- Add reboot actions to Amazon CloudWatch alarms
- Add recover actions to Amazon CloudWatch alarms
- Amazon CloudWatch alarm action scenarios

Add stop actions to Amazon CloudWatch alarms

You can create an alarm that stops an Amazon EC2 instance when a certain threshold has been met. For example, you may run development or test instances and occasionally forget to shut them

off. You can create an alarm that is triggered when the average CPU utilization percentage has been lower than 10 percent for 24 hours, signaling that it is idle and no longer in use. You can adjust the threshold, duration, and period to suit your needs, plus you can add an Amazon Simple Notification Service (Amazon SNS) notification so that you receive an email when the alarm is triggered.

Instances that use an Amazon EBS volume as the root volume can be stopped or terminated, whereas instances that use the instance store as the root volume can only be terminated. Data on instance store volumes is lost when the instance is terminated or stopped.

To create an alarm to stop an idle instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **Manage CloudWatch alarms**.

   Alternatively, you can choose the plus sign (

) in the **Alarm status** column.
4. On the **Manage CloudWatch alarms** page, do the following:

   a. Choose **Create an alarm**.

   b. To receive an email when the alarm is triggered, for **Alarm notification**, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the *Amazon Simple Notification Service Developer Guide*.

   c. Toggle on **Alarm action**, and choose **Stop**.

   d. For **Group samples by** and **Type of data to sample**, choose a statistic and a metric. In this example, choose **Average** and **CPU utilization**.

   e. For **Alarm When** and **Percent**, specify the metric threshold. In this example, specify **<=** and **10** percent.

   f. For **Consecutive period** and **Period**, specify the evaluation period for the alarm. In this example, specify **1** consecutive period of **5 Minutes**.

   g. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for **Alarm name**, enter a new name. Alarm names must contain only ASCII characters.

> **Note**
>
> You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.

h. Choose **Create**.

Add terminate actions to Amazon CloudWatch alarms

You can create an alarm that terminates an EC2 instance automatically when a certain threshold has been met (as long as termination protection is not enabled for the instance). For example, you might want to terminate an instance when it has completed its work, and you don't need the instance again. If you might want to use the instance later, you should stop the instance instead of terminating it. Data on instance store volumes is lost when the instance is terminated. For information about enabling and disabling termination protection for an instance, see Change instance termination protection.

To create an alarm to terminate an idle instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **Manage CloudWatch alarms**.

   Alternatively, you can choose the plus sign (

) in the **Alarm status** column.
4. On the **Manage CloudWatch alarms** page, do the following:

   a. Choose **Create an alarm**.

   b. To receive an email when the alarm is triggered, for **Alarm notification**, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the *Amazon Simple Notification Service Developer Guide*.

c. Toggle on **Alarm action**, and choose **Terminate**.

d. For **Group samples by** and **Type of data to sample**, choose a statistic and a metric. In this example, choose **Average** and **CPU utilization**.

e. For **Alarm When** and **Percent**, specify the metric threshold. In this example, specify **=>** and **10** percent.

f. For **Consecutive period** and **Period**, specify the evaluation period for the alarm. In this example, specify **24** consecutive periods of **1 Hour**.

g. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for **Alarm name**, enter a new name. Alarm names must contain only ASCII characters.

> **Note**
>
> You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.

h. Choose **Create**.

Add reboot actions to Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically reboots the instance. The reboot alarm action is recommended for Instance Health Check failures (as opposed to the recover alarm action, which is suited for System Health Check failures). An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance. When you reboot an instance, it remains on the same physical host, so your instance keeps its public DNS name, private IP address, and any data on its instance store volumes.

Rebooting an instance doesn't start a new instance billing period (with a minimum one-minute charge), unlike stopping and restarting your instance. Data on instance store volumes is retained when the instance is rebooted. The instance store volumes must be re-mounted into the filesystem after a reboot. For more information, see Reboot your Amazon EC2 instance.

Important

To avoid a race condition between the reboot and recover actions, avoid setting the same number of evaluation periods for a reboot alarm and a recover alarm. We recommend that you set reboot alarms to three evaluation periods of one minute each. For more information, see Evaluating an alarm in the *Amazon CloudWatch User Guide*.

To create an alarm to reboot an instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **Manage CloudWatch alarms**.

   Alternatively, you can choose the plus sign (
   
) in the **Alarm status** column.
4. On the **Manage CloudWatch alarms** page, do the following:

   a. Choose **Create an alarm**.

   b. To receive an email when the alarm is triggered, for **Alarm notification**, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the *Amazon Simple Notification Service Developer Guide*.

   c. Toggle on **Alarm action**, and choose **Reboot**.

   d. For **Group samples by** and **Type of data to sample**, choose a statistic and a metric. In this example, choose **Average** and **Status check failed: instance**.

   e. For **Consecutive period** and **Period**, specify the evaluation period for the alarm. In this example, enter **3** consecutive periods of **1 Minute**. If **1 Minute is disabled**, you must enable detailed monitoring, or you can choose **5 Minutes** instead.

   f. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for **Alarm name**, enter a new name. Alarm names must contain only ASCII characters.

   g. Choose **Create**.

Add recover actions to Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance. If the instance becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair, you can automatically recover the instance. Terminated instances cannot be recovered. A recovered instance is identical to the original instance, including the instance ID, private IP addresses, Elastic IP addresses, and all instance metadata.

CloudWatch prevents you from adding a recovery action to an alarm that is on an instance which does not support recovery actions.

When the `StatusCheckFailed_System` alarm is triggered, and the recover action is initiated, you are notified by the Amazon SNS topic that you chose when you created the alarm and associated the recover action. During instance recovery, the instance is migrated during an instance reboot, and any data that is in-memory is lost. When the process is complete, information is published to the SNS topic you've configured for the alarm. Anyone who is subscribed to this SNS topic receives an email notification that includes the status of the recovery attempt and any further instructions. You notice an instance reboot on the recovered instance.

> **Note**
>
> The recover action can be used only with `StatusCheckFailed_System`, not with `StatusCheckFailed_Instance`.

The following problems can cause system status checks to fail:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

The recover action is supported only on instances that meet certain characteristics. For more information, see Automatic instance recovery.

If your instance has a public IP address, it retains the public IP address after recovery.

Important

To avoid a race condition between the reboot and recover actions, avoid setting the same number of evaluation periods for a reboot alarm and a recover alarm. We recommend that you set recover alarms to two evaluation periods of one minute each. For more information, see Evaluating an alarm in the *Amazon CloudWatch User Guide*.

To create an alarm to recover an instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **Manage CloudWatch alarms**.

   Alternatively, you can choose the plus sign (

) in the **Alarm status** column.
4. On the **Manage CloudWatch alarms** page, do the following:

   a. Choose **Create an alarm**.

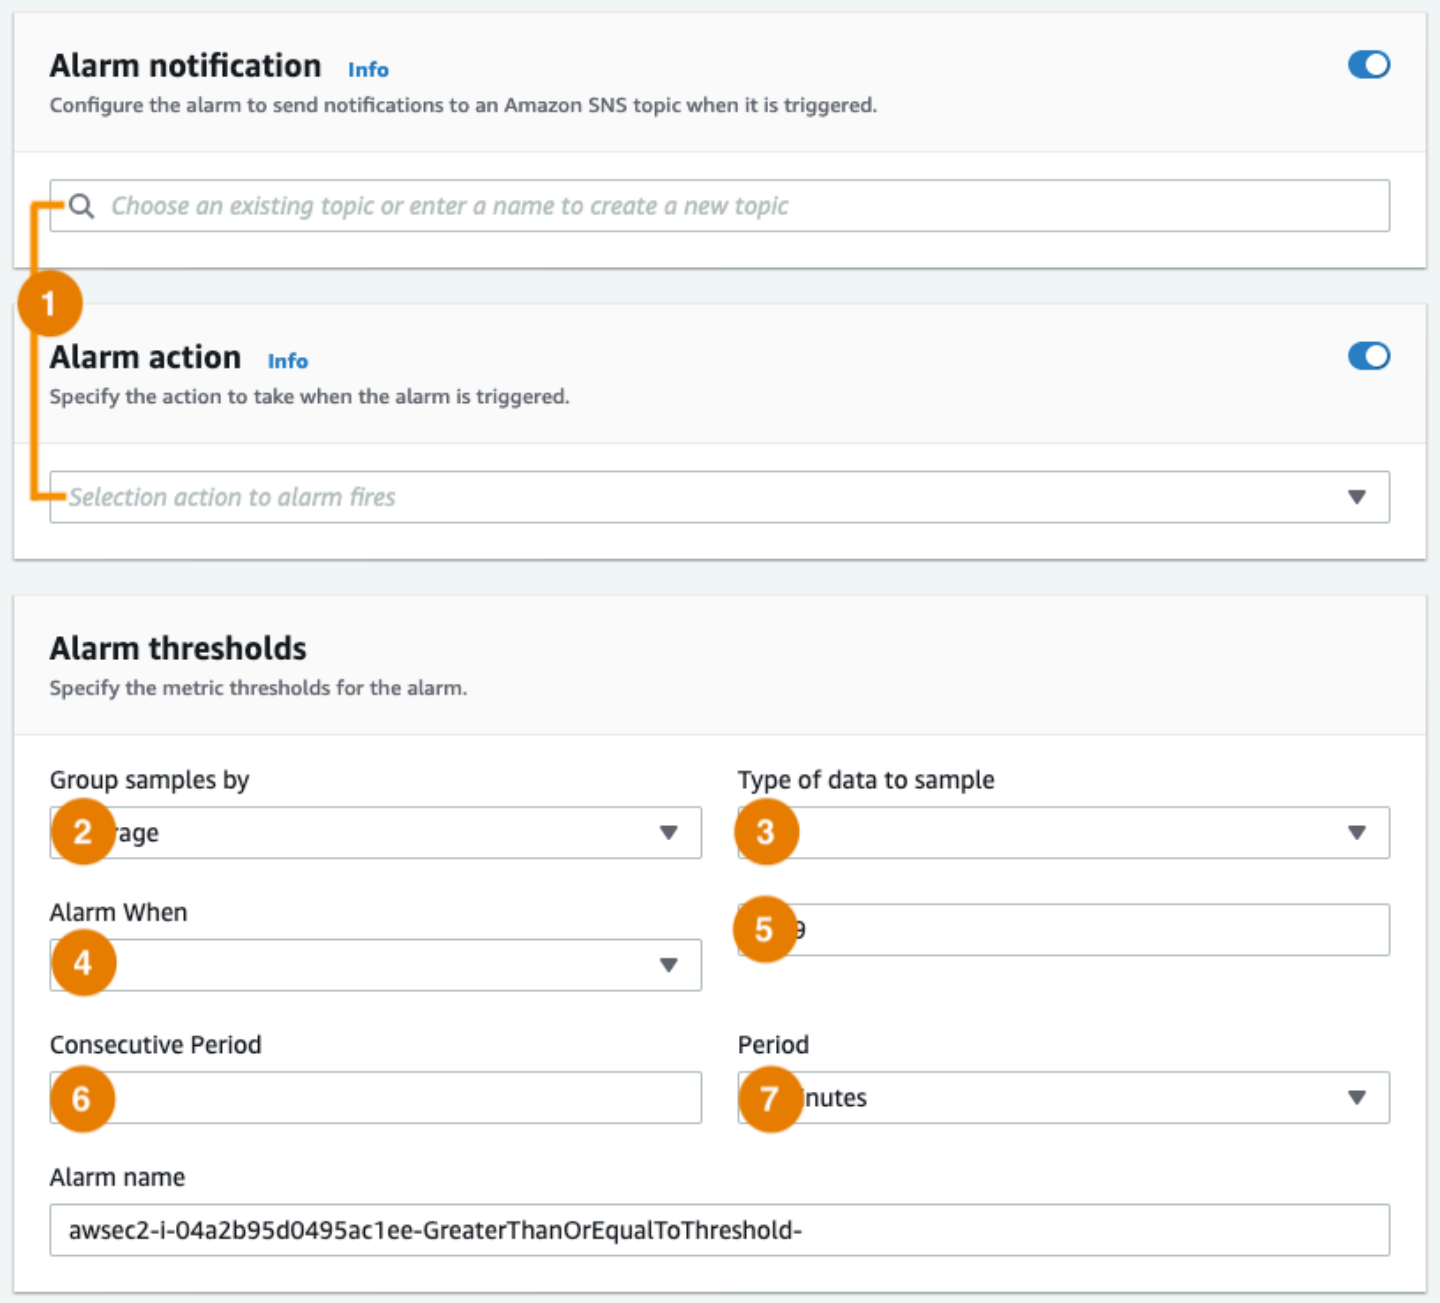
   b. To receive an email when the alarm is triggered, for **Alarm notification**, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the *Amazon Simple Notification Service Developer Guide*.

   Note

   Users must subscribe to the specified SNS topic to receive email notifications when the alarm is triggered. The AWS account root user always receives email notifications when automatic instance recovery actions occur, even if an SNS topic is not specified or the root user is not subscribed to the specified SNS topic.

   c. Toggle on **Alarm action**, and choose **Recover**.

   d. For **Group samples by** and **Type of data to sample**, choose a statistic and a metric. In this example, choose **Average** and **Status check failed: system**.



e. For **Consecutive period** and **Period**, specify the evaluation period for the alarm. In this example, enter **2** consecutive periods of **1 Minute**. If **1 Minute is disabled**, you must enable detailed monitoring, or you can choose **5 Minutes** instead.

f. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for **Alarm name**, enter a new name. Alarm names must contain only ASCII characters.

g. Choose **Create**.

Amazon CloudWatch alarm action scenarios

You can use the Amazon EC2 console to create alarm actions that stop or terminate an Amazon EC2 instance when certain conditions are met. In the following screen capture of the console page where you set the alarm actions, we've numbered the settings. We've also numbered the settings in the scenarios that follow, to help you create the appropriate actions.

Scenario 1: Stop idle development and test instances

Create an alarm that stops an instance used for software development or testing when it has been idle for at least an hour.

Setting	Value
1	Stop

Setting	Value
2	Maximum
3	CPU Utilization
4	<=
5	10%
6	1
7	1 Hour

Scenario 2: Stop idle instances

Create an alarm that stops an instance and sends an email when the instance has been idle for 24 hours.

Setting	Value
1	Stop and email
2	Average
3	CPU Utilization
4	<=
5	5%
6	24
7	1 Hour

Scenario 3: Send email about web servers with unusually high traffic

Create an alarm that sends email when an instance exceeds 10 GB of outbound network traffic per day.

Setting	Value
1	Email
2	Sum
3	Network Out
4	>
5	10 GB
6	24
7	1 Hour

Scenario 4: Stop web servers with unusually high traffic

Create an alarm that stops an instance and send a text message (SMS) if outbound traffic exceeds 1 GB per hour.

Setting	Value
1	Stop and send SMS
2	Sum
3	Network Out
4	>
5	1 GB
6	1
7	1 Hour

Scenario 5: Stop an impaired instance

Create an alarm that stops an instance that fails three consecutive status checks (performed at 5-minute intervals).

Setting	Value
1	Stop
2	Average
3	Status Check Failed: System
4	-
5	-
6	1
7	15 Minutes

Scenario 6: Terminate instances when batch processing jobs are complete

Create an alarm that terminates an instance that runs batch jobs when it is no longer sending results data.

Setting	Value
1	Terminate
2	Maximum
3	Network Out
4	<=
5	100,000 bytes
6	1

Setting	Value
7	5 Minutes

Automate Amazon EC2 using EventBridge

You can use Amazon EventBridge to automate your AWS services and respond automatically to system events, such as application availability issues or resource changes. Events from AWS services are delivered to EventBridge in near real time. You can create rules to indicate which events you're interested in, and the actions to take when an event matches a rule. The actions that can be automatically triggered include the following:

- Invoke an AWS Lambda function
- Invoke Amazon EC2 Run Command
- Relay the event to Amazon Kinesis Data Streams
- Activate an AWS Step Functions state machine
- Notify an Amazon SNS topic
- Notify an Amazon SQS queue

The following are examples of how you can use EventBridge with Amazon EC2:

- Activate a Lambda function whenever an instance enters the running state.
- Notify an Amazon SNS topic when an Amazon EBS volume is created or modified.
- Send a command to one or more Amazon EC2 instances using Amazon EC2 Run Command whenever a certain event in another AWS service occurs.

For more information, see the Amazon EventBridge User Guide.

Amazon EC2 event types

Amazon EC2 supports the following event types:

- EC2 AMI State Change
- EC2 Fast Launch State-change Notification

- EC2 Fleet Error
- EC2 Fleet Information
- EC2 Fleet Instance Change
- EC2 Fleet Spot Instance Request Change
- EC2 Fleet State Change
- EC2 Instance Rebalance Recommendation
- EC2 Instance State-change Notification
- EC2 Spot Fleet Error
- EC2 Spot Fleet Information
- EC2 Spot Fleet Instance Change
- EC2 Spot Fleet Spot Instance Request Change
- EC2 Spot Fleet State Change
- EC2 Spot Instance Interruption Warning
- EC2 Spot Instance Request Fulfillment
- EC2 ODCR Underutilization Notification

For information about the event types supported by Amazon EBS, see Amazon EventBridge for Amazon EBS.

Log Amazon EC2 API calls using AWS CloudTrail

The Amazon EC2 API is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all Amazon EC2 API calls as events. The calls captured include calls made by the console. Using the information collected by CloudTrail, you can determine the request that was made to the Amazon EC2 API, the IP address from which the request was made, and when it was made.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made on behalf of an IAM Identity Center user.

- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

CloudTrail is active in your AWS account when you create the account and you automatically have access to the CloudTrail **Event history**. The CloudTrail **Event history** provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an AWS Region. For more information, see Working with CloudTrail Event history in the *AWS CloudTrail User Guide*. There are no CloudTrail charges for viewing the **Event history**.

For an ongoing record of events in your AWS account past 90 days, create a trail or a CloudTrail Lake event data store.

CloudTrail trails

A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the AWS Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the AWS CLI. Creating a multi-Region trail is recommended because you capture activity in all AWS Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's AWS Region. For more information about trails, see Creating a trail for your AWS account and Creating a trail for an organization in the *AWS CloudTrail User Guide*.

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For more information about CloudTrail pricing, see AWS CloudTrail Pricing. For information about Amazon S3 pricing, see Amazon S3 Pricing.

CloudTrail Lake event data stores

CloudTrail Lake lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to Apache ORC format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into *event data stores*, which are immutable collections of events based on criteria that you select by applying advanced event selectors. The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see Working with AWS CloudTrail Lake in the *AWS CloudTrail User Guide*.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the pricing option you want to use for the event data store. The pricing

option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.

Amazon EC2 API management events in CloudTrail

Management events provide information about management operations that are performed on resources in your AWS account. These are also known as control plane operations. By default, CloudTrail logs management events.

All Amazon EC2 API actions are logged as management events. For a list of the API actions that are logged to CloudTrail, see the Amazon EC2 API Reference. For example, calls to the RunInstances, DescribeInstances, and StopInstances actions are logged as management events.

Amazon EC2 API event examples

An event represents a single request from any source and includes information about the requested API operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so events don't appear in any specific order.

The following log file record shows that a user terminated an instance.

```
{
   "Records":[
      {
         "eventVersion":"1.03",
         "userIdentity":{
            "type":"Root",
            "principalId":"123456789012",
            "arn":"arn:aws:iam::123456789012:root",
            "accountId":"123456789012",
            "accessKeyId":"AKIAIOSFODNN7EXAMPLE",
            "userName":"user"
         },
         "eventTime":"2016-05-20T08:27:45Z",
         "eventSource":"ec2.amazonaws.com",
         "eventName":"TerminateInstances",
         "awsRegion":"us-west-2",
         "sourceIPAddress":"198.51.100.1",
```

```
        "userAgent":"aws-cli/1.10.10 Python/2.7.9 Windows/7botocore/1.4.1",
        "requestParameters":{
           "instancesSet":{
              "items":[{
                 "instanceId":"i-1a2b3c4d"
              }]
           }
        },
        "responseElements":{
           "instancesSet":{
              "items":[{
                 "instanceId":"i-1a2b3c4d",
                 "currentState":{
                    "code":32,
                    "name":"shutting-down"
                 },
                 "previousState":{
                    "code":16,
                    "name":"running"
                 }
              }]
           }
        },
        "requestID":"be112233-1ba5-4ae0-8e2b-1c302EXAMPLE",
        "eventID":"6e12345-2a4e-417c-aa78-7594fEXAMPLE",
        "eventType":"AwsApiCall",
        "recipientAccountId":"123456789012"
     }
   ]
}
```

For information about CloudTrail record contents, see CloudTrail record contents in the *AWS CloudTrail User Guide*.

Audit connections made using EC2 Instance Connect

You can use AWS CloudTrail to audit the users that connect to your instances using EC2 Instance Connect.

To audit SSH activity through EC2 Instance Connect using the AWS CloudTrail console

1. Open the CloudTrail console at https://eusc-de-east-1.console.amazonaws-eusc.eu/cloudtrail/.

2. Verify that you are in the correct Region.
3. In the navigation pane, choose **Event history**.
4. For **Filter**, choose **Event source**, **ec2-instance-connect.amazonaws.com**.
5. (Optional) For **Time range**, select a time range.
6. Choose the **Refresh events** icon.
7. The page displays the events that correspond to the SendSSHPublicKey API calls. Expand an event using the arrow to view additional details, such as the user name and AWS access key that was used to make the SSH connection, and the source IP address.
8. To display the full event information in JSON format, choose **View event**. The **requestParameters** field contains the destination instance ID, OS username, and public key that were used to make the SSH connection.

```
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "ABCDEFGONGNOMOOCB6XYTQEXAMPLE",
        "arn": "arn:aws:iam::1234567890120:user/IAM-friendly-name",
        "accountId": "123456789012",
        "accessKeyId": "ABCDEFGUKZHNAW4OSN2AEXAMPLE",
        "userName": "IAM-friendly-name",
        "sessionContext": {
            "attributes": {
                "mfaAuthenticated": "false",
                "creationDate": "2018-09-21T21:37:58Z"}
        }
    },
    "eventTime": "2018-09-21T21:38:00Z",
    "eventSource": "ec2-instance-connect.amazonaws.com",
    "eventName": "SendSSHPublicKey ",
    "awsRegion": "us-west-2",
    "sourceIPAddress": "123.456.789.012",
    "userAgent": "aws-cli/1.15.61 Python/2.7.10 Darwin/16.7.0 botocore/1.10.60",
    "requestParameters": {
        "instanceId": "i-0123456789EXAMPLE",
        "osUser": "ec2-user",
        "SSHKey": {
            "publicKey": "ssh-rsa ABCDEFGHIJKLMNO01234567890EXAMPLE"
        }
     },
```

```
    "responseElements": null,
    "requestID": "1a2s3d4f-bde6-11e8-a892-f7ec64543add",
    "eventID": "1a2w3d4r5-a88f-4e28-b3bf-30161f75be34",
    "eventType": "AwsApiCall",
    "recipientAccountId": "0987654321"
}
```

If you have configured your AWS account to collect CloudTrail events in an S3 bucket, you can download and audit the information programmatically. For more information, see Getting and viewing your CloudTrail log files in the *AWS CloudTrail User Guide*.

Monitor .NET and SQL Server applications using CloudWatch Application Insights

CloudWatch Application Insights helps you monitor your .NET and SQL Server applications that use Amazon EC2 instances along with other AWS application resources. It identifies and sets up key metrics logs and alarms across your application resources and technology stack (for example, your Microsoft SQL Server database, web (IIS) and application servers, OS, load balancers, and queues). It continuously monitors the metrics and logs to detect and correlate anomalies and errors. When errors and anomalies are detected, Application Insights generates events that you can use to set up notifications or take actions. To aid with troubleshooting, it creates automated dashboards for the detected problems, which include correlated metric anomalies and log errors, along with additional insights to point you to the potential root cause. The automated dashboards help you to take swift remedial actions to keep your applications healthy and to prevent impact to the end users of your application.

Information provided about detected problems:

- A short summary of the problem
- The start time and date of the problem
- The problem severity: High/Medium/Low
- The status of the detected problem: In-progress/Resolved
- Insights: Automatically generated insights on the detected problem and possible root cause
- Feedback on insights: Feedback you have provided about the usefulness of the insights generated by CloudWatch Application Insights for .NET and SQL Server

- Related observations: A detailed view of the metric anomalies and error snippets of relevant logs related to the problem across various application components

Feedback

You can provide feedback on automatically generated insights on detected problems by designating them useful or not useful. Your feedback on the insights, along with your application diagnostics (metric anomalies and log exceptions), are used to improve the future detection of similar problems.

For more information, see the CloudWatch Application Insights documentation in the *Amazon CloudWatch User Guide*.

Understand codes for Amazon EC2 in billing and usage reports

When you use Amazon EC2, we include related codes in your AWS billing and usage reports. Reviewing these codes helps you understand your costs and usage patterns for Amazon EC2. Tracking and managing your expenses is essential for optimizing your costs.

The following tables describe the codes for Amazon EC2 that appear in your billing and usage reports. For a list of the Region codes used in the billing and usage reports, see AWS Region billing codes.

Billing codes for:

- Instances
- Bare metal instances
- Dedicated Hosts
- Dedicated Instances
- EBS optimization
- Capacity Reservations

Related resources

- the section called “Billing and purchasing options”
- the section called “Understand AMI billing”
- Amazon EC2 pricing

Instances

Code	Description	Units
region-BoxUsage :*instance-type*	The running time for On-Demand Instances.	Hours
region-HostBoxUsage :*instance-type*	The running time for instances on Dedicated Hosts.	Hours
region-SpotUsage :*instance-type*	The running time for Spot Instances.	Hours

Bare metal instances

Code	Description	Units
region-BoxUsage :*instance-family* .metal	The running time for bare metal On-Demand Instances.	Hours
region-HostBoxUsage :*instance-family* .metal	The running time for bare metal instances on Dedicated Hosts.	Hours
region-SpotUsage :*instance-family* .metal	The running time for bare metal Spot Instances.	Hours

Dedicated Hosts

Code	Description	Units
region-HostUsage :*host-type*	The time that Dedicated Hosts are provisioned.	Hours
region-ReservedHostUsage :*host-type*	The time that Dedicated Host Reservations are applied.	Hours

Dedicated Instances

Code	Description	Units
region-DedicatedUsage :*instance-type*	The running time for Dedicated Instances.	Hours + per-Region fee

EBS optimization

Code	Description	Units
region-EBSOptimized :*instance-type*	The time that EBS optimization is enabled.	Hours

Capacity Reservations

Code	Description	Units
region-Reservation :*instance-type*	The reserved instance time for Capacity Reservations.	Hours
region-UnusedBox :*instance-type*	The unused reserved instance time for Capacity Reservations.	Hours
region-DedicatedRes :*instance-type*	The reserved instance time for Dedicated Capacity Reservations.	Hours
region-UnusedDed :*instance-type*	The unused reserved instance time for Dedicated Capacity Reservations.	Hours

Create an inventory of your EC2 instances

Amazon EC2 provides on-demand, scalable computing capacity. An EC2 instance is a virtual server that runs in the AWS network.

The following table describes the key characteristics of an EC2 instance. A system administrator can use the guidance provided in this guide to get information about these characteristics and use it to configure functionally equivalent servers that run on premises or in the network of another Cloud Provider.

Characteristic	Description
Geographic location	Amazon EC2 is hosted in all AWS Regions world-wide. You select locations for your instances that put them close to your customers. You can launch instances in multiple locations.

Characteristic	Description
Hardware specifications	Amazon EC2 provides a wide selection of instance types, optimized for different use cases. The instance types that you select for your instances determine their compute, memory, networking, and storage resources.
Images	An Amazon Machine Image (AMI) includes the software to install on your instance at launch. This includes the operating system, software packages, and custom configurations.
IP addresses and DNS hostnames	Instances receive private IP addresses and a private DNS hostname. If you configure a public IP address for an instance, it also receives a public DNS hostname.
Security group rules	The security group rules associated with your instances determines which inbound traffic and outbound traffic is allowed.
User data	User data is made available to instances at launch. It consists of shell scripts (Linux) or PowerShell scripts (Windows).

Geographic location

Amazon EC2 is available in every AWS Region world-wide. Each Region is a separate geographic area. You can lower network latency when you select Regions for your servers that are close to the majority of your users.

You can use Amazon EC2 Global View to list your Amazon EC2 instances across all Regions. With the AWS Management Console and the API, you must list the instances for each Region individually.

Why this matters

After you determine where your instances are located, you can decide whether to deploy functionally equivalent servers in the same locations or different locations, depending on your needs.

To get a summary of your EC2 instances across all Regions

1. Open the Amazon EC2 Global View console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2globalview/home.
2. On the **Region explorer** tab, under **Summary**, check the resource count for **Instances**, which includes the number of instances and the number of Regions. Choose the underlined text to see how the instance count is spread across Regions.
3. On the **Global search** tab, select the client filter **Resource type = Instance**. You can filter the results further by specifying a Region or a tag.

To get the number of EC2 instances in a Region using the AWS CLI

Use the following describe-instances command to count the instances in the specified Region. You must run this command in each Region where you have instances.

```
aws ec2 describe-instances \
    --region us-east-2 \
    --query "length(Reservations[*].Instances[])"
```

The following is example output.

```
27
```

To get a list of the instance IDs instead of the count of instances, use the following `--query` parameter instead.

```
--query "Reservations[*].Instances[].InstanceId"
```

Hardware specifications

The instance type that you specify for an EC2 instance determines the compute, memory, storage, and networking resources that are available to it. Each instance family offers a different balance of compute, memory, network, and storage resources. For more information, see the Amazon EC2 Instance Types Guide.

Why these matter

After you determine the hardware specifications for your instances, you can decide the minimum specifications required for functionally equivalent servers.

To get a summary of the instance types used by your instances

Use the following describe-instances command. The **sed** command removes lines with brackets and empty lines. You must run this command in each Region where you have instances.

```
aws ec2 describe-instances \
    --query "Reservations[*].Instances[].InstanceType" | sed 's/[][]//g;/^$/d' | sort |
 uniq -c | sort -nr
```

The following is example output.

```
  20    "c6i.4xlarge",
   5    "t2.micro",
   2    "g6e.2xlarge",
```

To get information about specific instance types

Use the following describe-instance-types command to describe the instance types. The `--query` parameter includes only the specified fields in the output. These are the basic characteristics. You can include any additional fields that you need, or you can refer to Amazon EC2 instance type specifications in the *Amazon EC2 Instance Types Guide*.

```
aws ec2 describe-instance-types \
    --instance-types c6i.4xlarge t2.micro g6e.2xlarge \
    --query "InstanceTypes[*].
[InstanceType,VCpuInfo.DefaultVCpus,MemoryInfo.SizeInMiB,NetworkInfo.NetworkPerformance]"
 \
    --output table
```

The following is example output. The columns are instance type, vCPUs, memory (GiB), and network bandwidth (Gbps).

```
-------------------------------------------------------
|                DescribeInstanceTypes                |
+--------------+-----+--------+----------------------+
```

```
|  t2.micro    |  1  |  1024  |  Low to Moderate     |
|  c6i.4xlarge |  16 |  32768 |  Up to 12.5 Gigabit  |
|  g6e.2xlarge |  8  |  65536 |  Up to 20 Gigabit    |
+--------------+-----+--------+----------------------+
```

Images

An Amazon Machine Image (AMI) provides the software that's installed on your instance at launch, such as the operating system, services, development tools, and applications. You can export an AMI to other formats for use with other servers.

Why these matter

After you determine the AMIs for your instances, you can plan the images required for functionally equivalent servers. It might be possible to export your AMIs to a format that you can use elsewhere. Alternatively, you might need to connect to an instance that you launched from each AMI, confirm what's installed and how it's configured, and ensure that you have a copy of everything that you need.

To get the AMIs for your instances

Use the following describe-instances command. The **sed** command removes lines with brackets and empty lines. You must run this command in each Region where you have instances.

```
aws ec2 describe-instances \
    --query "Reservations[*].Instances[].ImageId" | sed 's/[][]//g;/^$/d' | sort | uniq
 -c | sort -nr
```

The following is example output.

```
20     "ami-0a70b9d193ae8a79",
 5     "ami-07d9cf938edb0739b",
 2     "ami-09245d5773578a1d6",
```

To get information about specific AMIs

Use the following describe-images command. The `--query` parameter includes only the specified fields in the output. You can include any additional fields that you need.

```
aws ec2 describe-images \
```

```
    --image-id ami-0a70b9d193ae8a79 ami-07d9cf938edb0739b ami-09245d5773578a1d6 \
    --query "Images[*].
{ID:ImageId,CreateDate:CreationDate,Name:Name,Description:Description}"
```

The following is example output.

```
[
    {
        "ID": "ami-0a70b9d193ae8a799",
        "CreateDate": "2025-03-01T02:22:41.000Z",
        "Name": "web-server-3.1",
        "Description": "Image for web servers"
    },
    {
        "ID": "ami-07d9cf938edb0739b",
        "CreateDate": "2025-02-01T23:59:03.000Z",
        "Name": "awesome-application-11.5",
        "Description": "Image for Awesome Application"
    },
    {
        "ID": "ami-09245d5773578a1d6",
        "CreateDate": "2025-01-31T02:22:41.000Z",
        "Name": "monitoring-4.2",
        "Description": "Monitoring software"
    }
]
```

To create a VM file from an AMI

Use the export-image command. The supported image formats are VHD (compatible with Citrix Xen and Microsoft Hyper-V), VMDK (compatible with VMware ESX and VMware vSphere), and raw format (compatible with KVM and Xen hypervisors). For information about the requirements and limitations of VM Import/Export, see VM Import/Export requirements.

IP addresses and DNS hostnames

Your users connect to your EC2 instances over the internet using their public DNS hostnames. The public DNS hostname of an EC2 instance resolves to its public IP address. EC2 instances can communicate with each other using their private IP addresses.

Why these matter

IP addresses allow devices to communicate with each other over a local network or the internet. By noting the IP addresses and DNS names of your instances, you can help to ensure that functionally equivalent servers can communicate with the same clients or devices as your instances. For example, you can update your load balancer configuration or the DNS records that you created for your DNS provider.

To get the IP addresses and DNS hostnames for your instances

Use the following describe-instances command. You must run this command in each Region where you have instances. The `--query` parameter includes only the specified fields in the output. You can include any additional fields that you need.

```
aws ec2 describe-instances \
    --query "Reservations[*].Instances[].[InstanceId,PrivateIpAddress,PublicDnsName]" \
    --output table
```

The following is example output. The columns are instance ID, private IPv4 address, and public IPv4 DNS name.

```
----------------------------------------------------------------------------------
|                                DescribeInstances
 |
+---------------------+------------+-------------------------------------------------
+
| i-0bac57d7472c89bac | 10.0.2.139 | ec2-192-0-2-142.us-east-2.compute.amazonaws.com
 |
| i-0fa8b7678975a3fff | 10.0.14.85 | ec2-198-51-100-56.us-east-2.compute.amazonaws.com
 |
  ...
  ...
| i-08fd74f3f1595fdbd | 10.0.1.241 | ec2-203.0.113.13.us-east-2.compute.amazonaws.com
 |
+---------------------+------------+-------------------------------------------------
+
```

Security group rules

A security group acts as a virtual firewall. After you associate a security group with an EC2 instance, its rules allow inbound and outbound traffic for the EC2 instance over specific ports and protocols.

Why these matter

After you determine the inbound traffic allowed to reach your server and the outbound traffic allowed to leave your server, you can plan the firewall rules needed for functionally equivalent servers.

To get the security groups for your instances

Use the following describe-instances command. The **sed** command removes lines with brackets and empty lines. You must run this command in each Region where you have instances.

```
aws ec2 describe-instances \
    --query "Reservations[*].Instances[].SecurityGroups[].GroupId" | sed 's/[][]//g;/^
$/d' | sort | uniq -c | sort -nr
```

The following is example output.

```
27     "sg-01dd3383691d02f42",
10     "sg-08c77cc910c0b3b2c",
 2     "sg-00f4e409629f1a42d",
```

To get the inbound rules for a security group

Use the following describe-security-group-rules command to display the rules for the specified security group where `IsEgress` is `false`.

```
aws ec2 describe-security-group-rules \
    --filters Name=group-id,Values=sg-01dd3383691d02f42 \
    --query 'SecurityGroupRules[?IsEgress==`false`]'
```

The following is example output. The first rule is the default inbound rule, which allows inbound traffic from all resources that are assigned to this security group. The other rule allows SSH traffic from the IP addresses in the specified prefix list. To describe the CIDR blocks in a prefix list, use the describe-prefix-lists command.

```
[
    {
        "SecurityGroupRuleId": "sgr-06c8b42574a91db1b",
        "GroupId": "sg-01dd3383691d02f42",
        "GroupOwnerId": "123456789012",
        "IsEgress": false,
        "IpProtocol": "-1",
        "FromPort": -1,
```

```
        "ToPort": -1,
        "ReferencedGroupInfo": {
            "GroupId": "sg-01dd3383691d02f42",
            "UserId": "123456789012"
        },
        "Tags": [],
        "SecurityGroupRuleArn": "arn:aws:ec2:us-west-2:123456789012:security-group-
rule/sgr-06c8b42574a91db1b"
    },
    {
        "SecurityGroupRuleId": "sgr-0886a5d46afcd1758",
        "GroupId": "sg-01dd3383691d02f42",
        "GroupOwnerId": "123456789012",
        "IsEgress": false,
        "IpProtocol": "tcp",
        "FromPort": 22,
        "ToPort": 22,
        "PrefixListId": "pl-f8a6439125e7bf465",
        "Tags": [],
        "SecurityGroupRuleArn": "arn:aws-eusc:ec2:us-east-2:123456789012:security-
group-rule/sgr-0886a5d46afcd1758"
    }
]
```

To get the outbound rules for a security group

Use the following describe-security-group-rules command to display the rules for the specified security group where `IsEgress` is `true`.

```
aws ec2 describe-security-group-rules \
    --filters Name=group-id,Values=sg-01dd3383691d02f42 \
    --query 'SecurityGroupRules[?IsEgress==`true`]'
```

The following is example output. It contains only the default outbound rule, which allows all outbound IPv4 traffic.

```
[
    {
        "SecurityGroupRuleId": "sgr-048f09a719247dce7",
        "GroupId": "sg-01dd3383691d02f42",
        "GroupOwnerId": "123456789012",
        "IsEgress": true,
```

```
        "IpProtocol": "-1",
        "FromPort": -1,
        "ToPort": -1,
        "CidrIpv4": "0.0.0.0/0",
        "Tags": [],
        "SecurityGroupRuleArn": "arn:aws-eusc:ec2:us-east-2:123456789012:security-
group-rule/sgr-048f09a719247dce7"
    }
]
```

User data

When you launch an EC2 instance, you can pass a shell script to the instance using user data. Note that user data is base64 encoded, so you need to decode the user data to read the script.

Why this matters

If you're running commands at launch as part of setting up your instances, you might need to perform the same tasks when setting up functionally equivalent servers.

To view the decoded user data for an instance

Use the following describe-instance-attribute command. The **base64** command decodes the user data.

```
aws ec2 describe-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --attribute userData \
    --output text \
    --query "UserData.Value" | base64 --decode
```

The following is example output.

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

Related resources

The following are additional characteristics of EC2 instances:

- Key pairs
- Storage
- Tags

You can verify whether you're using the following to launch EC2 instances or distribute traffic between your EC2 instances:

- Auto Scaling groups
- EC2 Fleet
- Elastic Load Balancing

Troubleshoot issues with Amazon EC2 instances

The following procedures and tips can help you troubleshoot issues with your Amazon EC2 instances.

Issues

- Troubleshoot Amazon EC2 instance launch issues
- Troubleshoot Amazon EC2 instance stop issues
- Troubleshoot Amazon EC2 instance termination issues
- Troubleshoot an unreachable Amazon EC2 instance
- Troubleshoot issues connecting to your Amazon EC2 Linux instance
- Troubleshoot Amazon EC2 Linux instances with failed status checks
- Troubleshoot an Amazon EC2 Linux instance booting from wrong volume
- Troubleshoot issues connecting to your Amazon EC2 Windows instance
- Troubleshoot Amazon EC2 Windows instance start issues
- Troubleshoot issues with Amazon EC2 Windows instances
- Kernel debugging for Windows instances over the network
- Troubleshoot your Windows instance using SAC
- Reset the Windows administrator password for an Amazon EC2 Windows instance
- Troubleshoot Sysprep issues with Amazon EC2 Windows instances
- Troubleshoot impaired Amazon EC2 Linux instance using EC2Rescue
- Troubleshoot impaired Amazon EC2 Windows instance using EC2Rescue
- EC2 Serial Console for instances
- Send a diagnostic interrupt to debug an unreachable Amazon EC2 instance

Troubleshoot Amazon EC2 instance launch issues

The following are troubleshooting tips to help you solve issues when launching an Amazon EC2 instance.

Launch Issues

- Invalid device name

- Instance limit exceeded
- Insufficient instance capacity
- The requested configuration is currently not supported. Please check the documentation for supported configurations.
- Instance terminates immediately
- Insufficient permissions
- High CPU usage shortly after Windows starts (Windows instances only)
- Launching an IMDSv1-enabled instance fails

Invalid device name

Description

You get the `Invalid device name` *`device_name`* error when you try to launch a new instance.

Cause

If you get this error when you try to launch an instance, the device name specified for one or more volumes in the request has an invalid device name. Possible causes include:

- The device name might be in use by the selected AMI.
- The device name might be reserved for root volumes.
- The device name might be used for another volume in the request.
- The device name might not be valid for the operating system.

Solution

To resolve the issue:

- Ensure that the device name is not used in the AMI that you selected. Run the following command to view the device names used by the AMI.

```
aws ec2 describe-images --image-id ami-0abcdef1234567890 --query
 'Images[*].BlockDeviceMappings[].DeviceName'
```

- Ensure that you are not using a device name that is reserved for root volumes. For more information, see Available device names.

- Ensure that each volume specified in your request has a unique device name.
- Ensure that the device names that you specified are in the correct format. For more information, see Available device names.

Instance limit exceeded

Description

You get the `InstanceLimitExceeded` error when you try to launch a new instance or restart a stopped instance.

Cause

If you get an `InstanceLimitExceeded` error when you try to launch a new instance or restart a stopped instance, you have reached the limit on the number of instances that you can launch in a Region. When you create your AWS account, we set default limits on the number of instances you can run on a per-Region basis.

Solution

You can request an instance limit increase on a per-region basis. For more information, see Amazon EC2 service quotas.

Insufficient instance capacity

Description

You get the `InsufficientInstanceCapacity` error when you try to launch a new instance or restart a stopped instance.

Cause

If you get this error when you try to launch an instance or restart a stopped instance, AWS does not currently have enough available On-Demand capacity to fulfill your request.

Solution

To resolve the issue, try the following:

- Wait a few minutes and then submit your request again; capacity can shift frequently.

- Submit a new request with a reduced number of instances. For example, if you're making a single request to launch 15 instances, try making 3 requests for 5 instances, or 15 requests for 1 instance instead.
- If you're launching an instance, submit a new request without specifying an Availability Zone.
- If you're launching an instance, submit a new request using a different instance type (which you can resize at a later stage). For more information, see Amazon EC2 instance type changes.
- If you are launching instances into a cluster placement group, you can get an insufficient capacity error.

The requested configuration is currently not supported. Please check the documentation for supported configurations.

Description

You get the `Unsupported` error when you try to launch a new instance because the instance configuration is not supported.

Cause

The error message provides additional details. For example, an instance type or instance purchasing option might not be supported in the specified Region or Availability Zone.

Solution

Try a different instance configuration. To search for an instance type that meets your requirements, see Find an Amazon EC2 instance type.

Instance terminates immediately

Description

Your instance goes from the `pending` state to the `terminated` state.

Cause

The following are a few reasons why an instance might immediately terminate:

- You've exceeded your EBS volume limits. For more information, see Amazon EBS volume limits for Amazon EC2 instances.

- An EBS snapshot is corrupted.
- The root EBS volume is encrypted and you do not have permissions to access the KMS key for decryption.
- A snapshot specified in the block device mapping for the AMI is encrypted and you do not have permissions to access the KMS key for decryption or you do not have access to the KMS key to encrypt the restored volumes.
- The Amazon S3-backed AMI that you used to launch the instance is missing a required part (an image.part.*xx* file).

For more information, get the termination reason using one of the following methods.

To get the termination reason using the Amazon EC2 console

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**, and select the instance.
3. On the first tab, find the reason next to **State transition reason**.

To get the termination reason using the AWS CLI

1. Use the describe-instances command and specify the instance ID.

```
aws ec2 describe-instances --instance-id i-1234567890abcdef0
```

2. Review the JSON response returned by the command and note the values in the `StateReason` response element.

   The following code block shows an example of a `StateReason` response element.

```
"StateReason": {
  "Message": "Client.VolumeLimitExceeded: Volume limit exceeded",
  "Code": "Server.InternalError"
},
```

To get the termination reason using AWS CloudTrail

For more information, see Viewing events with CloudTrail event history in the *AWS CloudTrail User Guide*.

Solution

Depending on the termination reason, take one of the following actions:

- **`Client.VolumeLimitExceeded: Volume limit exceeded`** — Delete unused volumes. You can submit a request to increase your volume limit.
- **`Client.InternalError: Client error on launch`** — Ensure that you have the permissions required to access the AWS KMS keys used to decrypt and encrypt volumes. For more information, see Using key policies in AWS KMS in the *AWS Key Management Service Developer Guide*.

Insufficient permissions

Description

You get the `"errorMessage": "You are not authorized to perform this operation."` error when you try to launch a new instance, and the launch fails.

Cause

If you get this error when you try to launch an instance, you don't have the required IAM permissions to launch the instance.

Possible missing permissions include:

- `ec2:RunInstances`
- `iam:PassRole`

Other permissions might also be missing. For the list of permissions required to launch an instance, see the example IAM policies under Example: Use the EC2 launch instance wizard and Launch instances (RunInstances).

Solution

To resolve the issue:

- If you are making requests as an IAM user, verify that you have the following permissions:
  - `ec2:RunInstances` with a wildcard resource ("*")

- `iam:PassRole` with the resource matching the role ARN (for example, `arn:aws-eusc:iam::999999999999:role/ExampleRoleName`)
- If you don't have the preceding permissions, edit the IAM policy associated with the IAM role or user to add the missing required permissions.

If your issue is not resolved and you continue receiving a launch failure error, you can decode the authorization failure message included in the error. The decoded message includes the permissions that are missing from the IAM policy. For more information, see How do I decode an authorization failure message after I receive an "UnauthorizedOperation" error during an EC2 instance launch?

High CPU usage shortly after Windows starts (Windows instances only)

> **Note**
>
> This troubleshooting tip is for Windows instances only.

If Windows Update is set to **Check for updates but let me choose whether to download and install them** (the default instance setting) this check can consume anywhere from 50 - 99% of the CPU on the instance. If this CPU consumption causes problems for your applications, you can manually change Windows Update settings in **Control Panel** or you can use the following script in the Amazon EC2 user data field:

```
reg add "HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\WindowsUpdate\Auto Update" /v
 AUOptions /t REG_DWORD /d 3 /f net stop wuauserv net start wuauserv
```

When you run this script, specify a value for /d. The default value is 3. Possible values include the following:

1. Never check for updates
2. Check for updates but let me choose whether to download and install them
3. Download updates but let me choose whether to install them
4. Install updates automatically

After you modify the user data for your instance, you can run it. For more information, see Run commands on your Windows instance at launch.

Launching an IMDSv1-enabled instance fails

Description

You get an `UnsupportedOperation` exception with the following message:

```
You can't launch instances with IMDSv1 because httpTokensEnforced
is enabled for this account. Either launch the instance with
httpTokens=required or contact your account owner to disable
httpTokensEnforced using the ModifyInstanceMetadataDefaults API or the
account settings in the EC2 console.
```

Cause

This error is thrown when you attempt to launch a new instance to be IMDSv1 enabled (`httpTokens = optional`) in an account where the EC2 account settings or an AWS Organization declarative policy enforces the use of IMDSv2 (`httpTokensEnforced = enabled`).

Solution

If you're ready to use IMDSv2 only, launch your instance with IMDSv1 disabled (`httpTokens = required`). To check if you're ready, see Transition to using Instance Metadata Service Version 2.

If you still require IMDSv1 support on new or existing instances, you'll need to disable IMDSv2 enforcement for the account in the Region. To disable IMDSv2 enforcement, set `HttpTokensEnforced` to `disabled`. For more information, see ModifyInstanceMetadataDefaults in the Amazon EC2 API Reference. If you prefer to configure this setting using the console, see Enforce IMDSv2 at the account level.

Troubleshoot Amazon EC2 instance stop issues

If your Amazon EBS-backed instance appears stuck in the `stopping` state, the issue might be with the underlying host computer.

To resolve the issue, follow these steps:

1. **Force stop the instance**

   Use the Amazon EC2 console or the AWS CLI to force stop the instance. For the steps, see Force stop an instance.

The instance will first attempt a graceful shutdown, which includes flushing file system caches and metadata (although you can optionally bypass the graceful shutdown). If the graceful shutdown fails to complete within the timeout period, the instance shuts down forcibly without flushing the file system caches and metadata.

2. **After force stop**

   Perform file system check and repair procedures.

   > **Important**
   >
   > Performing these procedures is crucial because a forced stop prevents flushing of file system caches and metadata.

3. **If force stop fails**

   If, after 10 minutes, the instance has not stopped, do the following:

   a. Post a request for help on AWS re:Post. To help expedite a resolution, include the instance ID, and describe the steps that you've already taken.

   b. Alternatively, if you have a support plan, create a technical support case in the Support Center.

   c. While waiting for assistance, you can create a replacement instance if needed. For the steps, see (Optional) Create a replacement instance.

There is no cost for instance usage while an instance is in the `stopping` state or in any other state except `running`. You are only charged for instance usage when an instance is in the `running` state.

Contents

- Force stop an instance
- (Optional) Create a replacement instance

Force stop an instance

You can force an instance to stop. If, after 10 minutes, the instance has not stopped, post a request for help on AWS re:Post. To help expedite a resolution, include the instance ID, and describe the

steps that you've already taken. Alternatively, if you have a support plan, create a technical support case in the Support Center.

> **Note**
>
> Using the console, you can force an instance to stop while the instance is in the `stopping` state only. Using the AWS CLI, you can force an instance to stop while the instance is in the `pending`, `running`, or `stopping` state.

Console

To force stop an instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Instance state**, **Force stop instance**.

   Note that **Force stop instance** is only available in the console if your instance is in the `stopping` state. If your instance is in another state (except `shutting-down` and `terminated`) you can use the AWS CLI to force stop your instance.
4. (Optional) To bypass the graceful OS shutdown during the force stop, select the **Skip OS shutdown** checkbox.
5. Choose **Force stop**.

AWS CLI

To force stop an instance

Use the stop-instances command with the `--force` option.

```
aws ec2 stop-instances \
    --instance-ids i-1234567890abcdef0 \
    --force
```

To bypass the graceful OS shutdown during force stop, include the `--skip-os-shutdown` option.

```
aws ec2 stop-instances \
```

```
    --instance-ids i-1234567890abcdef0 \
    --force \
    --skip-os-shutdown
```

PowerShell

To force stop an instance

Use the Stop-EC2Instance cmdlet and set `-Enforce` to `true`.

```
Stop-EC2Instance `
    -InstanceId i-1234567890abcdef0 `
    -Enforce $true
```

To bypass the graceful OS shutdown during force stop, include `-SkipOsShutdown $true`.

```
Stop-EC2Instance `
    -InstanceId i-1234567890abcdef0 `
    -Enforce $true `
    -SkipOsShutdown $true
```

(Optional) Create a replacement instance

While you are waiting for assistance from AWS re:Post or the Support Center, you can create a replacement instance if needed. Create an AMI from the stuck instance, and launch a new instance using the new AMI.

Important

You can create a replacement instance if the stuck instance produces system status checks only, as instance status checks will result in the AMI copying over an exact replica of the broken operating system. After you've confirmed the status message, create the AMI and launch a new instance using the new AMI.

Console

To create a replacement instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.

2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Actions**, **Image and templates**, **Create image**.
4. On the **Create image** page, do the following:

   a. Enter a name and description for the AMI.

   b. Clear **Reboot instance**.

   c. Choose **Create image**.

   For more information, see the section called “Create an AMI from an instance”.
5. Launch a new instance from the AMI and verify that the new instance is working.
6. Select the stuck instance, and choose **Actions**, **Instance state**, **Terminate (delete) instance**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

If you are unable to create an AMI from the instance as described in the previous procedure, you can set up a replacement instance as follows:

(Alternate) To create a replacement instance using the console

1. Select the instance and choose **Description**, **Block devices**. Select each volume and make note of its volume ID. Be sure to note which volume is the root volume.
2. In the navigation pane, choose **Volumes**. Select each volume for the instance, and choose **Actions**, **Create Snapshot**.
3. In the navigation pane, choose **Snapshots**. Select the snapshot that you just created, and choose **Actions**, **Create Volume**.
4. Launch an instance with the same operating system as the stuck instance. Note the volume ID and device name of its root volume.
5. In the navigation pane, choose **Instances**, select the instance that you just launched, and choose **Instance state**, **Stop instance**.
6. In the navigation pane, choose **Volumes**, select the root volume of the stopped instance, and choose **Actions**, **Detach Volume**.
7. Select the root volume that you created from the stuck instance, choose **Actions**, **Attach Volume**, and attach it to the new instance as its root volume (using the device name that you made note of). Attach any additional non-root volumes to the instance.

8. In the navigation pane, choose **Instances** and select the replacement instance. Choose **Instance state**, **Start instance**. Verify that the instance is working.
9. Select the stuck instance, choose **Instance state**, **Terminate (delete) instance**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

AWS CLI

To create a replacement instance

1. Create an AMI from the stuck instance using the create-image command with the `--no-reboot` option.

```
aws ec2 create-image \
    --instance-id i-1234567890abcdef0 \
    --name "my-replacement-ami" \
    --description "AMI for replacement instance" \
    --no-reboot
```

2. Launch a new instance from the AMI that you just created, using the run-instances command.
3. Verify that the new instance is working.
4. (Optional) Terminate the stuck instance using the terminate-instances command.

```
aws ec2 terminate-instances --instance-ids i-1234567890abcdef0
```

PowerShell

To create a replacement instance

1. Create an AMI from the stuck instance using the New-EC2Image cmdlet and set `-NoReboot` to `true`.

```
New-EC2Image `
    -InstanceId i-1234567890abcdef0 `
    -Name "my-replacement-ami" `
    -Description "AMI for replacement instance" `
    -NoReboot $true
```

2. Launch a new instance from the AMI that you just created, using the New-EC2Instance cmdlet.
3. Verify that the new instance is working.
4. (Optional) Terminate the stuck instance using the Remove-EC2Instance cmdlet.

```
Remove-EC2Instance -InstanceId i-1234567890abcdef0
```

Troubleshoot Amazon EC2 instance termination issues

Shutting down or deleting your instance is known as instance termination. The following information can help you troubleshoot issues when you terminate your instance.

You are not billed for any instance usage while an instance is not in the `running` state. In other words, when you terminate an instance, you stop incurring charges for that instance as soon as its state changes to `shutting-down`.

Instance terminates immediately

Several issues can cause your instance to terminate immediately on start-up. See Instance terminates immediately for more information.

Delayed instance termination

If your instance remains in the `shutting-down` state longer than a few minutes, it might be because:

- The instance is running shutdown scripts.
- There's a problem with the underlying host computer.

After several hours in the `shutting-down` state, Amazon EC2 treats the instance as stuck and forcibly terminates it.

To resolve a stuck instance yourself:

1. **Force terminate the instance**

   Use the Amazon EC2 console or the AWS CLI to force terminate the instance. For the steps, see Force terminate an instance.

The instance will first attempt a graceful shutdown, which includes flushing file system caches and metadata (although you can optionally bypass the graceful shutdown). If the graceful shutdown fails to complete within the timeout period, the instance shuts down forcibly without flushing the file system caches and metadata.

2. **If force terminate fails**

   If, after several hours, the instance has not terminated and it appears stuck terminating, do the following:

   a. Post a request for help on AWS re:Post. To help expedite a resolution, include the instance ID, and describe the steps that you've already taken.

   b. Alternatively, if you have a support plan, create a technical support case in the Support Center.

Force terminate an instance

If it appears that your instance is stuck terminating, you can force your instance to terminate. If, after several hours, the instance has not terminated, post a request for help to AWS re:Post. To help expedite a resolution, include the instance ID and describe the steps that you've already taken. Alternatively, if you have a support plan, create a technical support case in the Support Center.

Console

To force terminate an instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Instance state**, **Force terminate instance**.

   Note that **Force terminate instance** is only available in the console if your instance is in the `stopping` state. If your instance is in another state (except `shutting-down` and `terminated`) you can use the AWS CLI to force terminate your instance.

4. (Optional) To bypass the graceful OS shutdown during the force terminate, select the **Skip OS shutdown** checkbox.
5. Choose **Force terminate**.

AWS CLI

To force terminate an instance

Use the terminate-instances command with the `--force` option.

```
aws ec2 terminate-instances \
    --instance-ids i-1234567890abcdef0 \
    --force
```

To bypass the graceful OS shutdown during force terminate, include the `--skip-os-shutdown` option.

```
aws ec2 terminate-instances \
    --instance-ids i-1234567890abcdef0 \
    --force \
    --skip-os-shutdown
```

PowerShell

To force terminate an instance

Use the Remove-EC2Instance cmdlet and set `-Enforce` to `true`.

```
Remove-EC2Instance `
    -InstanceId i-1234567890abcdef0 `
    -Enforce $true
```

To bypass the graceful OS shutdown during force terminate, include `-SkipOsShutdown $true`.

```
Remove-EC2Instance `
    -InstanceId i-1234567890abcdef0 `
    -Enforce $true `
    -SkipOsShutdown $true
```

Terminated instance still displayed

After you terminate an instance, it remains visible for a short while before being deleted. The state shows as `terminated`. If the entry is not deleted after several hours, contact Support.

Error: The instance may not be terminated. Modify its 'disableApiTermination' instance attribute

If you try to terminate an instance and get the `The instance i-1234567890abcdef0 may not be terminated. Modify its 'disableApiTermination' instance attribute` error message, it indicates that the instance has been enabled for termination protection. Termination protection prevents the instance from being accidentally terminated.

You must disable termination protection before you can terminate the instance.

For more information, see Change instance termination protection.

Instances automatically launched or terminated

Generally, the following behaviors mean that you've used Amazon EC2 Auto Scaling, EC2 Fleet, or Spot Fleet to scale your computing resources automatically based on criteria that you've defined:

- You terminate an instance and a new instance launches automatically.
- You launch an instance and one of your instances terminates automatically.
- You stop an instance and it terminates and a new instance launches automatically.

To stop automatic scaling, find the Auto Scaling group or the fleet that is launching the instances and either set its capacity to 0 or delete it.

Troubleshoot an unreachable Amazon EC2 instance

The following information can help you troubleshoot unreachable Amazon EC2 instances. You can capture screenshots or access console output to help diagnose problems and determine if you should reboot your instance. For unreachable Windows instances, troubleshoot by reviewing screenshots returned by the service.

Contents

- Instance reboot
- Instance console output
- Capture a screenshot of an unreachable instance
- Common screenshots to troubleshoot unreachable Windows instances

- Instance recovery when a host computer fails
- Instance appeared offline and unexpectedly rebooted

Instance reboot

The ability to reboot instances that are otherwise unreachable is valuable for both troubleshooting and general instance management.

Just as you can reset a computer by pressing the reset button, you can reset EC2 instances using the Amazon EC2 console, CLI, or API. For more information, see Reboot your Amazon EC2 instance.

Instance console output

Console output is a valuable tool for problem diagnosis. It is especially useful for troubleshooting kernel problems and service configuration issues that could cause an instance to terminate or become unreachable before its SSH daemon can be started.

- **Linux instances** – The instance console output displays the exact console output that would normally be displayed on a physical monitor attached to a computer. The console output returns buffered information that was posted shortly after an instance transition state (start, stop, reboot, and terminate). The posted output is not continuously updated; only when it is likely to be of the most value.
- **Windows instances** – The instance console output includes the last three system event log errors.

Only the instance owner can access the console output.

You can retrieve the latest serial console output during the instance lifecycle. This option is only supported on Nitro-based instances.

Console

To get console output

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the left navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Monitor and troubleshoot**, **Get system log**.

AWS CLI

To get console output

Use the get-console-output command.

```
aws ec2 get-console-output --instance-id i-1234567890abcdef0
```

PowerShell

To get console output

Use the Get-EC2ConsoleOutput cmdlet.

```
Get-EC2ConsoleOutput -InstanceId i-1234567890abcdef0
```

Capture a screenshot of an unreachable instance

If you are unable to connect to your instance, you can capture a screenshot of your instance and view it as an image. The image can provide visibility as to the status of the instance, and allows for quicker troubleshooting.

You can generate screenshots while the instance is running or after it has crashed. The image is generated in JPG format and is no larger than 100 kb. There is no data transfer cost for the screenshot.

Limitations

This feature is not supported for the following:

- Bare metal instances (instances of type `*.metal`)
- Instance is using an NVIDIA GRID driver
- Instances powered by Arm-based Graviton processors
- Windows instances on AWS Outposts
- Windows instances on AWS Local Zones

Region support

This feature is not available in the following Regions:

- Asia Pacific (Thailand)
- Mexico (Central)
- GovCloud Regions

Console

To get a screenshot of an instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the left navigation pane, choose **Instances**.
3. Select the instance to capture.
4. Choose **Actions**, **Monitor and troubleshoot**, **Get instance screenshot**.
5. Choose **Download**, or open the context (right-click) menu for the image to download and save it.

AWS CLI

To capture a screenshot of an instance

Use the get-console-screenshot command. The output is base64-encoded.

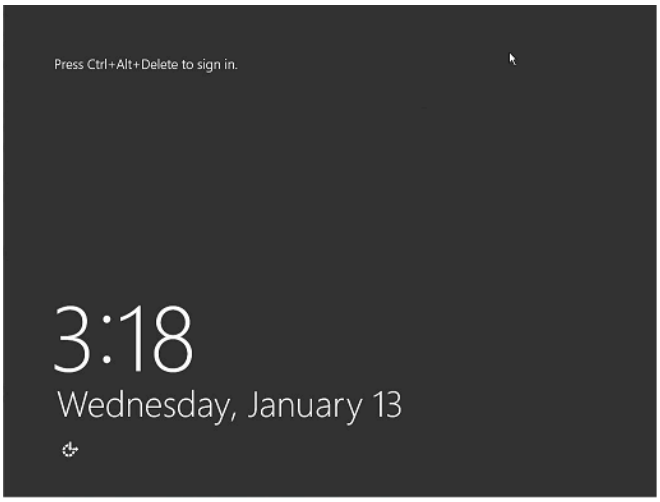
```
aws ec2 get-console-screenshot --instance-id i-1234567890abcdef0
```

PowerShell

To capture a screenshot of an instance

Use the Get-EC2ConsoleScreenshot cmdlet. The output is base64-encoded.

```
Get-EC2ConsoleScreenshot -InstanceId i-1234567890abcdef0
```



Common screenshots to troubleshoot unreachable Windows instances

You can use the following information to help you troubleshoot an unreachable Windows instance based on screenshots returned by the service.

- Log on screen (Ctrl+Alt+Delete)
- Recovery console screen
- Windows boot manager screen
- Sysprep screen
- Getting ready screen
- Windows Update screen
- Chkdsk

Log on screen (Ctrl+Alt+Delete)

Console Screenshot Service returned the following.

If an instance becomes unreachable during logon, there could be a problem with your network configuration or Windows Remote Desktop Services. An instance can also be unresponsive if a process is using large amounts of CPU.

Network configuration

Use the following information to verify that your AWS, Microsoft Windows, and local (or on-premises) network configurations aren't blocking access to the instance.

AWS network configuration

Configuration	Verify
Security group configuration	Verify that port 3389 is open for your security group. Verify you are connecting to the right public IP address. If the instance was not associated with an Elastic IP, the public IP changes after the instance stops/starts. For more information, see Remote Desktop can't connect to the remote computer.
VPC configuration (Network ACLs)	Verify that the access control list (ACL) for your Amazon VPC is not blocking access. For information, see Network ACLs in the *Amazon VPC User Guide*.
VPN configuration	If you are connecting to your VPC using a virtual private network (VPN), verify VPN tunnel connectivity. For more information, see Troubleshooting AWS Client VPN: Tunnel connectivity issues to a VPC.

Windows network configuration

Configuration	Verify
Windows Firewall	Verify that Windows Firewall isn't blocking connections to your instance. Disable Windows Firewall as described in bullet 7 of the remote desktop troubleshooting section, Remote Desktop can't connect to the remote computer.
Advanced TCP/IP configuration (Use of static IP)	The instance may be unresponsive because you configured a static IP address. For a VPC, create a network interface and attach it to the instance.

Local or on-premises network configuration

Verify that a local network configuration isn't blocking access. Try to connect to another instance in the same VPC as your unreachable instance. If you can't access another instance, work with your local network administrator to determine whether a local policy is restricting access.

Remote Desktop Services issues

If the instance can't be reached during logon, there could a problem with Remote Desktop Services (RDS) on the instance.

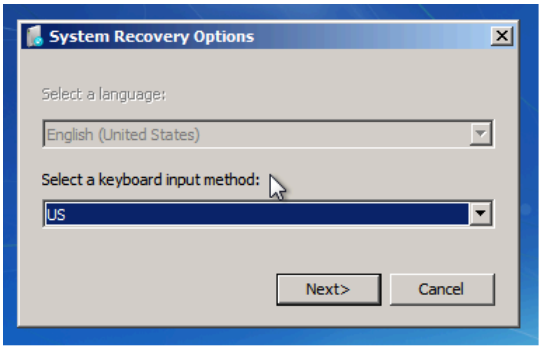
> **Tip**
>
> You can use the `AWSSupport-TroubleshootRDP` runbook to check and modify various settings that might affect Remote Desktop Protocol (RDP) connections. For more information, see `AWSSupport-TroubleshootRDP` in the *AWS Systems Manager Automation runbook reference*.

Remote Desktop Services configuration

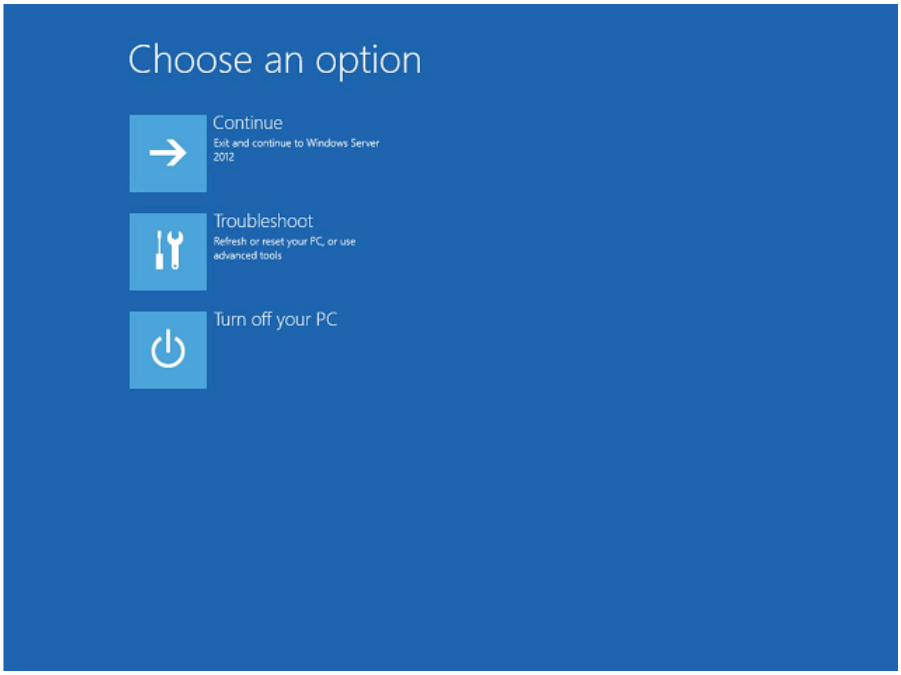
Configuration	Verify
RDS is running	Verify that RDS is running on the instance. Connect to the instance using the Microsoft Management Console (MMC) Services snap-in (`services.msc`). In the list of services, verify that **Remote Desktop Services** is **Running**. If it isn't, start it and then set the startup type to **Automatic**. If you can't connect to the instance by using the Services snap-in, detach the root volume from the instance, take a snapshot of the volume or create an AMI from it, attach the original volume to another instance in the same Availability Zone as a secondary volume, and modify the Start registry key. When you are finished, reattach the root volume to the original instance.
RDS is enabled	Even if the service is started, it might be disabled. Detach the root volume from the instance, take a snapshot of the volume or create an AMI from it, attach the original volume to another instance in the same Availability Zone as a secondary volume,

Configuration	Verify
	and enable the service by modifying the **Terminal Server** registry key as described in Enable Remote Desktop on an EC2 instance with remote registry. When you are finished, reattach the root volume to the original instance.

High CPU usage



Check the **CPUUtilization (Maximum)** metric on your instance by using Amazon CloudWatch. If **CPUUtilization (Maximum)** is a high number, wait for the CPU to go down and try connecting again. High CPU usage can be caused by:



- Windows Update
- Security Software Scan
- Custom Startup Script
- Task Scheduler

For more information, see Get Statistics for a Specific Resource in the *Amazon CloudWatch User Guide*. For additional troubleshooting tips, see High CPU usage shortly after Windows starts (Windows instances only).

Recovery console screen

Console Screenshot Service returned the following.

The operating system might boot into the Recovery console and get stuck in this state if the `bootstatuspolicy` is not set to `ignoreallfailures`. Use the following procedure to change the `bootstatuspolicy` configuration to `ignoreallfailures`.

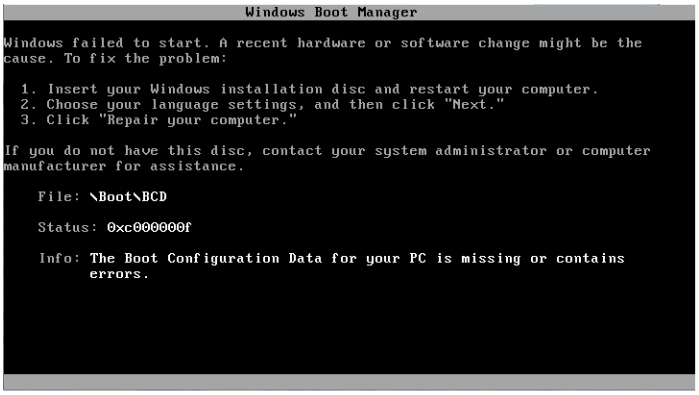
By default, the policy configuration for public Windows AMIs provided by AWS is set to `ignoreallfailures`.

1. Stop the unreachable instance.
2. Create a snapshot of the root volume. The root volume is attached to the instance as `/dev/sda1`.

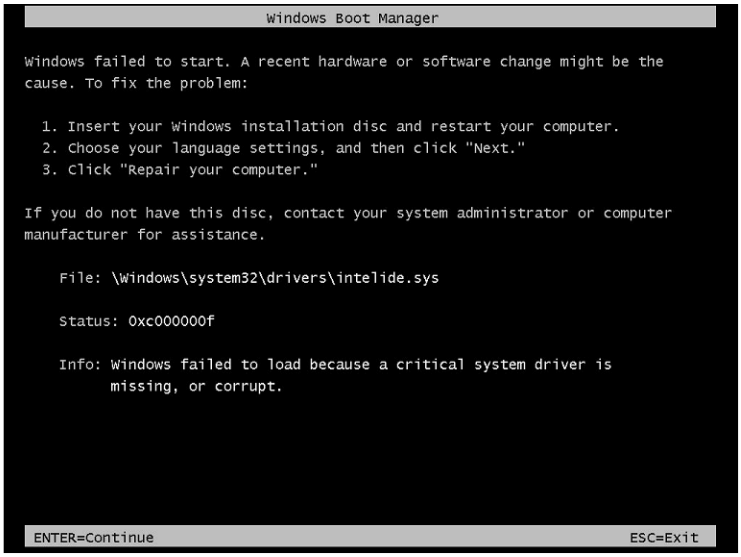
   Detach the root volume from the unreachable instance, take a snapshot of the volume or create an AMI from it, and attach it to another instance in the same Availability Zone as a secondary volume.

   > **Warning**
   >
   > If your temporary instance and the original instance were launched using the same AMI, you must complete additional steps or you won't be able to boot the original instance after you restore its root volume because of a disk signature collision. If you must create a temporary instance using the same AMI, to avoid a disk signature collision, complete the steps in Disk signature collision.

Alternatively, select a different AMI for the temporary instance. For example, if the original instance uses an AMI for Windows Server 2016, launch the temporary instance using an AMI for Windows Server 2019.



3. Log in to the instance and run the following command from a command prompt to change the `bootstatuspolicy` configuration to `ignoreallfailures`.

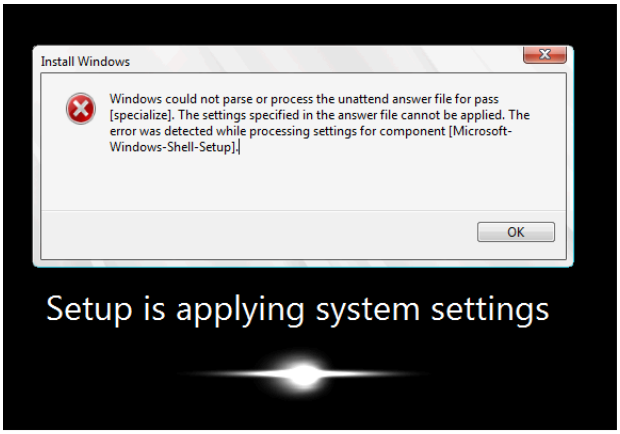


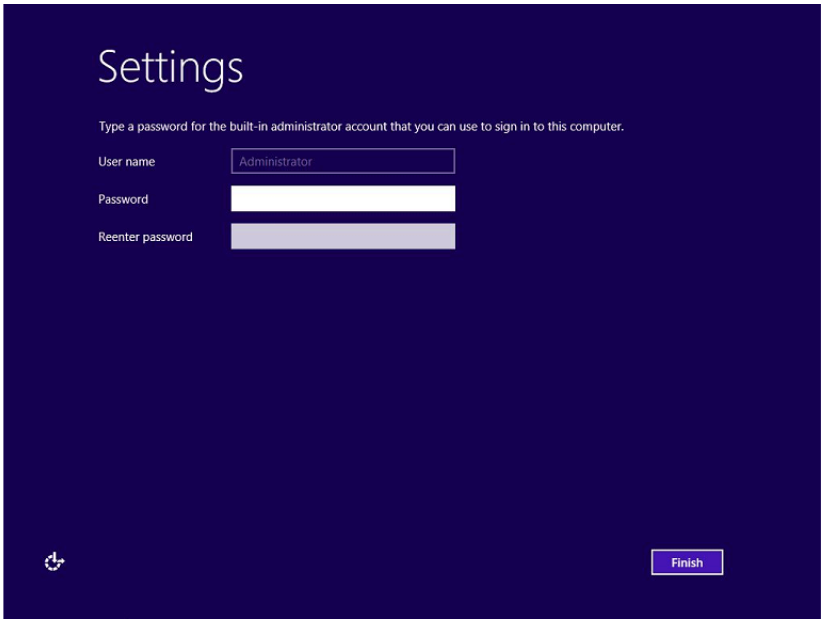
```
bcdedit /store Drive Letter:\boot\bcd /set {default} bootstatuspolicy
 ignoreallfailures
```

4. Reattach the volume to the unreachable instance and start the instance again.

Windows boot manager screen

Console Screenshot Service returned the following.

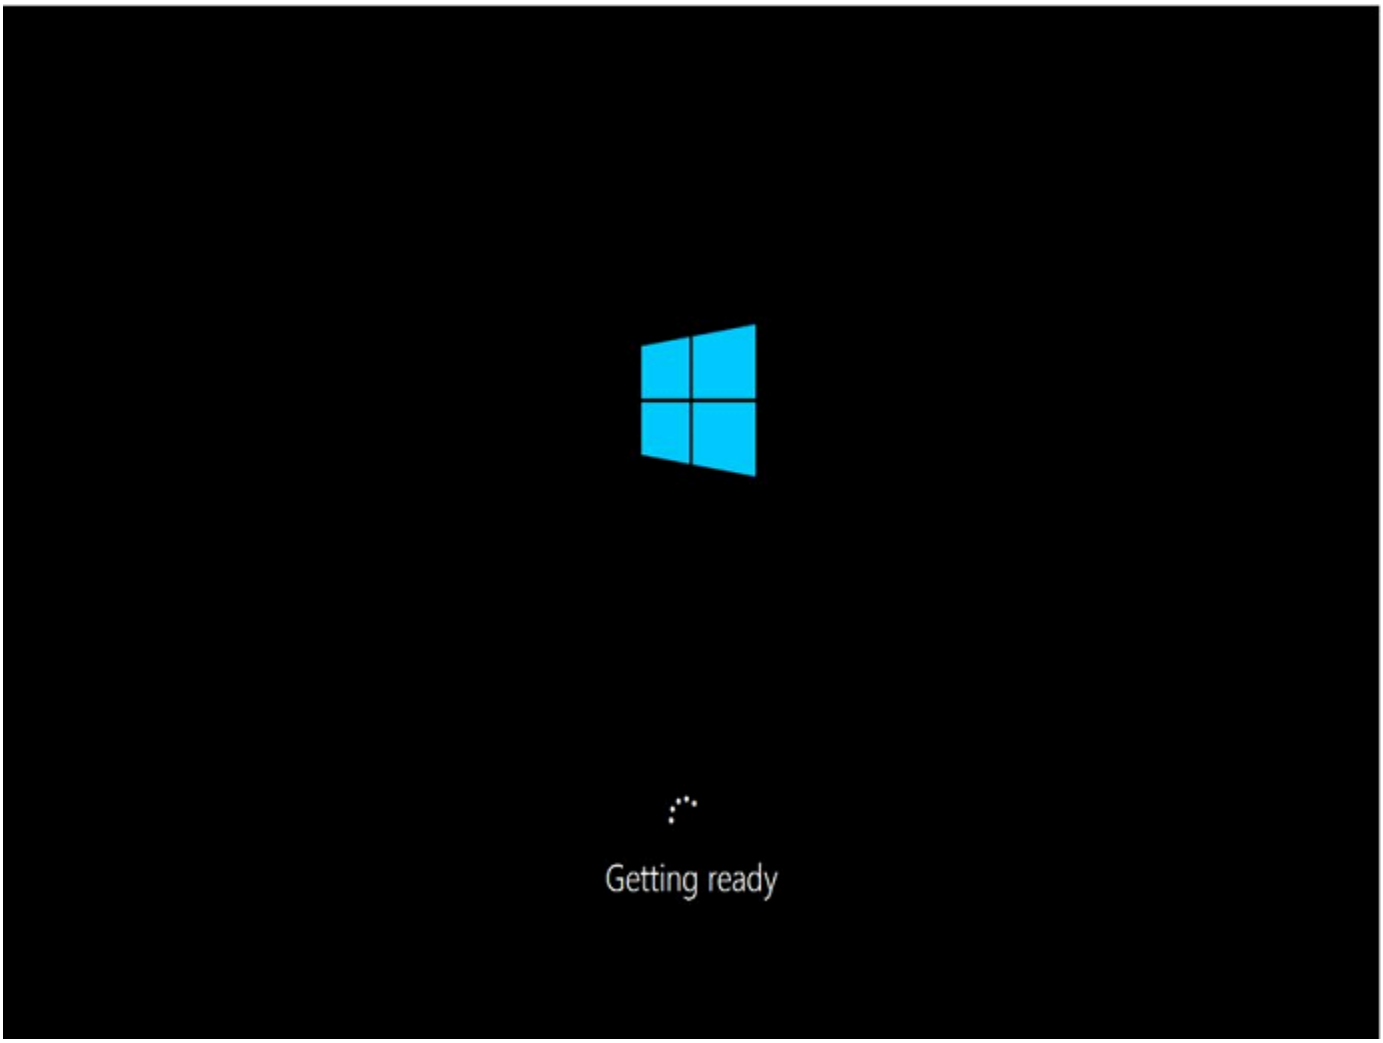




The operating system experienced a fatal corruption in the system file and/or the registry. When the instance is stuck in this state, you should recover the instance from a recent backup AMI or launch a replacement instance. If you need to access data on the instance, detach any root volumes from the unreachable instance, take a snapshot of those volume or create an AMI from them, and attach them to another instance in the same Availability Zone as a secondary volume.

Sysprep screen

Console Screenshot Service returned the following.



You may see this screen if you did not use the EC2Config Service to call Sysprep or if the operating system failed while running Sysprep. You can reset the password using EC2Rescue. Otherwise, see Create an Amazon EC2 AMI using Windows Sysprep.

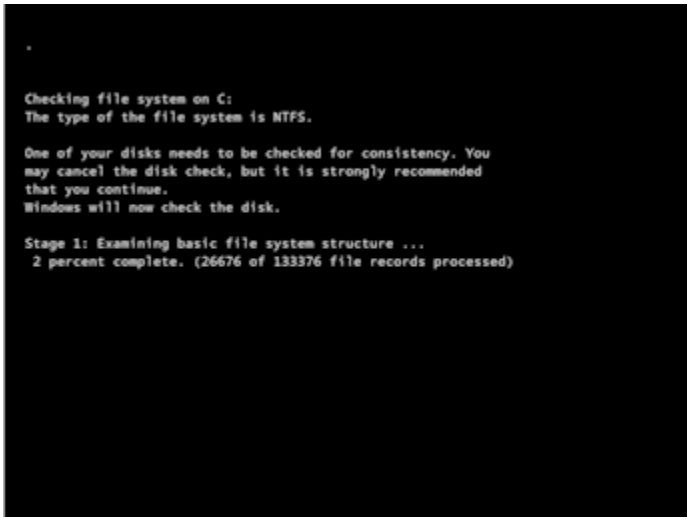
Getting ready screen

Console Screenshot Service returned the following.

Refresh the Instance Console Screenshot Service repeatedly to verify that the progress ring is spinning. If the ring is spinning, wait for the operating system to start up. You can also check the **CPUUtilization (Maximum)** metric on your instance by using Amazon CloudWatch to see if the operating system is active. If the progress ring is not spinning, the instance may be stuck at the boot process. Reboot the instance. If rebooting does not solve the problem, recover the instance from a recent backup AMI or launch a replacement instance. If you need to access data on the instance, detach the root volume from the unreachable instance, take a snapshot of the volume or create an AMI from it. Then attach it to another instance in the same Availability Zone as a secondary volume.

Windows Update screen

Console Screenshot Service returned the following.



The Windows Update process is updating the registry. Wait for the update to finish. Do not reboot or stop the instance as this may cause data corruption during the update.

> **Note**
>
> The Windows Update process can consume resources on the server during the update. If you experience this problem often, consider using faster instance types and faster EBS volumes.

Chkdsk

Console Screenshot Service returned the following.

Windows is running the chkdsk system tool on the drive to verify file system integrity and fix logical file system errors. Wait for process to complete.

Instance recovery when a host computer fails

If there is an unrecoverable issue with the hardware of an underlying host computer, AWS may schedule an instance stop event. You are notified of such an event ahead of time by email.

To recover an Amazon EBS-backed instance running on a host computer that failed

1. Back up any important data on your instance store volumes to Amazon EBS or Amazon S3.
2. Stop the instance.
3. Start the instance.
4. Restore any important data.

For more information, see Stop and start Amazon EC2 instances.

To recover an instance with an instance store root volume running on a host computer that failed

1. Create an AMI from the instance.
2. Upload the image to Amazon S3.
3. Back up important data to Amazon EBS or Amazon S3.
4. Terminate the instance.
5. Launch a new instance from the AMI.
6. Restore any important data to the new instance.

Instance appeared offline and unexpectedly rebooted

If your instance appears to have been offline and then unexpectedly rebooted, it might have undergone automatic instance recovery. This happens when AWS detects that the instance is unavailable due to an underlying hardware or software issue, and either simplified automatic recovery or CloudWatch action based recovery is enabled on the instance.

During the recovery process, AWS attempts to restore the instance's availability by migrating it to different hardware. To verify whether automatic instance recovery occurred for your instance, see Verify if automatic instance recovery occurred.

> **Note**
>
> If your workload or application is unresponsive, check whether it's running on the instance. If it's not, start it manually. To prevent this issue in the future, implement a recovery plan to ensure your workload or application functions properly after instance recovery.

Troubleshoot issues connecting to your Amazon EC2 Linux instance

The following information and common errors can help you troubleshoot connecting to your Linux instance.

Connection issues

- Common causes for connection issues
- Error connecting to your instance: Connection timed out
- Error: unable to load key ... Expecting: ANY PRIVATE KEY
- Error: User key not recognized by server
- Error: Permission denied or connection closed by [instance] port 22
- Error: Unprotected private key file
- Error: Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"
- Error: Host key verification failed
- Error: Server refused our key or No supported authentication methods available
- Cannot ping instance
- Error: Server unexpectedly closed network connection
- Error: Host key validation failed for EC2 Instance Connect
- Can't connect to Ubuntu instance using EC2 Instance Connect
- I've lost my private key. How can I connect to my instance?

Common causes for connection issues

We recommend that you start to troubleshoot instance connection problems by verifying that you have accurately performed the following tasks.

Verify the username for your instance

You can connect to your instance using the username for your user account or the default username for the AMI that you used to launch your instance.

- **Get the username for your user account.**

  For more information about how to create a user account, see Manage system users on your Amazon EC2 Linux instance.

- **Get the default username for the AMI that you used to launch your instance.**

AMI used to launch instance	Default username
Amazon Linux	`ec2-user`
CentOS	`centos` or `ec2-user`
Debian	`admin`
Fedora	`fedora` or `ec2-user`
FreeBSD	`ec2-user`
RHEL	`ec2-user` or `root`
SUSE	`ec2-user` or `root`
Ubuntu	`ubuntu`
Oracle	`ec2-user`
Bitnami	`bitnami`
Rocky Linux	`rocky`
Other	Check with the AMI provider

Verify that your security group rules allow traffic

Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. The default security group for the VPC does not allow incoming SSH traffic by default. The security group created by the launch instance wizard enables SSH traffic by default. For steps to add a rule for inbound SSH traffic to your Linux instance, see Rules to connect to instances from your computer. For steps to verify, see Error connecting to your instance: Connection timed out.

Verify that your instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready to accept connection requests. Check your instance to make sure it is running and has passed its status checks.

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. Verify the following:
   a. In the **Instance state** column, verify that your instance is in the `running` state.
   b. In the **Status check** column, verify that your instance has passed all status checks.

Verify that you've satisfied all prerequisites to connect

Ensure that you have all the information that you need to connect. For more information, see Connect to your Linux instance using SSH.

Connect from Linux or macOS X

If your local computer operating system is Linux or macOS X, check the following for specific prerequisites for connecting to a Linux instance:

- SSH client
- EC2 Instance Connect
- AWS Systems Manager Session Manager

Connect from Windows

If your local computer operating system is Windows, check the following for specific prerequisites for connecting to a Linux instance:

- OpenSSH
- PuTTY
- AWS Systems Manager Session Manager
- Windows Subsystem for Linux

Check if the instance is a managed instance

User-initiated connections to managed instances are not allowed. To determine if the instance is managed, find the **Managed** field for the instance. If the value is **true**, it's a managed instance. For more information, see Amazon EC2 managed instances.

Error connecting to your instance: Connection timed out

If you try to connect to your instance and get the error message `Network error: Connection timed out` or `Error connecting to [instance], reason: -> Connection timed out: connect`, try the following:

Check your security group rules.

You need a security group rule that allows inbound traffic from your local computer's public IPv4 address on the proper port.

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. On the **Security** tab at the bottom of the console page, under **Inbound rules**, check the list of rules that are in effect for the selected instance. Verify that there is a rule that allows traffic from your local computer to port 22 (SSH).

   If your security group does not have a rule that allows inbound traffic from your local computer, add a rule to your security group. For more information, see Rules to connect to instances from your computer.
4. For the rule that allows inbound traffic, check the **Source** field. If the value is a single IP address, and if the IP address is not static, a new IP address will be assigned each time you restart your computer. This will result in the rule not including your computer's IP address traffic. The IP address might not be static if your computer is on a corporate network, or you're connecting through an internet service provider (ISP), or your computer IP address is dynamic and changes each time you restart your computer. To ensure that your security group rule

allows inbound traffic from your local computer, instead of specifying a single IP address for **Source**, rather specify the range of IP addresses used by your client computers.

For more information about security group rules, see Security group rules in the *Amazon VPC User Guide*.

Check the route table for the subnet.

You need a route that sends all traffic destined outside the VPC to the internet gateway for the VPC.

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. On the **Networking** tab, make note of the values for **VPC ID** and **Subnet ID**.
4. Open the Amazon VPC console at https://eusc-de-east-1.console.amazonaws-eusc.eu/vpc/.
5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create internet gateway**, enter a name for the internet gateway, and choose **Create internet gateway**. Then, for the internet gateway you created, choose **Actions**, **Attach to VPC**, select your VPC, and then choose **Attach internet gateway** to attach it to your VPC.
6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route table** tab, verify that there is a route with `0.0.0.0/0` as the destination and the internet gateway for your VPC as the target. If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (`::/0`) that points to the internet gateway. Otherwise, do the following:

   a. Choose the ID of the route table (rtb-*xxxxxxxx*) to navigate to the route table.

   b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use `0.0.0.0/0` as the destination and the internet gateway as the target. For IPv6, choose **Add route**, use `::/0` as the destination and the internet gateway as the target.

   c. Choose **Save routes**.

Check the network access control list (ACL) for the subnet.

The network ACLs must allow inbound SSH traffic from your local IP address on port 22. It must also allow outbound traffic to the ephemeral ports (1024-65535).

1. Open the Amazon VPC console at https://eusc-de-east-1.console.amazonaws-eusc.eu/vpc/.
2. In the navigation pane, choose **Subnets**.
3. Select your subnet.
4. On the **Network ACL** tab, for **Inbound rules**, verify that the rules allow inbound traffic from your computer on the required port. Otherwise, delete or modify the rule that is blocking the traffic.
5. For **Outbound rules**, verify that the rules allow outbound traffic to your computer on the ephemeral ports. Otherwise, delete or modify the rule that is blocking the traffic.

If your computer is on a corporate network

Ask your network administrator whether the internal firewall allows inbound and outbound traffic from your computer on port 22.

If you have a firewall on your computer, verify that it allows inbound and outbound traffic from your computer on port 22.

Check that your instance has a public IPv4 address.

If not, you can associate an Elastic IP address with your instance. For more information, see Elastic IP addresses.

Check the CPU load on your instance; the server may be overloaded.

AWS automatically provides data such as Amazon CloudWatch metrics and instance status, which you can use to see how much CPU load is on your instance and, if necessary, adjust how your loads are handled. For more information, see Monitor your instances using CloudWatch.

- If your load is variable, you can automatically scale your instances up or down using Auto Scaling and Elastic Load Balancing.
- If your load is steadily growing, you can move to a larger instance type. For more information, see Amazon EC2 instance type changes.

To connect to your instance using an IPv6 address, check the following:

- Your subnet must be associated with a route table that has a route for IPv6 traffic (`::/0`) to an internet gateway.

- Your security group rules must allow inbound traffic from your local IPv6 address on port 22.
- Your network ACL rules must allow inbound and outbound IPv6 traffic.
- If you launched your instance from an older AMI, it might not be configured for DHCPv6 (IPv6 addresses are not automatically recognized on the network interface). For more information, see Configure IPv6 on your instances in the *Amazon VPC User Guide*.
- Your local computer must have an IPv6 address, and must be configured to use IPv6.

Error: unable to load key ... Expecting: ANY PRIVATE KEY

If you try to connect to your instance and get the error message, `unable to load key ... Expecting: ANY PRIVATE KEY`, the file in which the private key is stored is incorrectly configured. If the private key file ends in `.pem`, it might still be incorrectly configured. A possible cause for an incorrectly configured private key file is a missing certificate.

If the private key file is incorrectly configured, follow these steps to resolve the error

1. Create a new key pair. For more information, see Create a key pair using Amazon EC2.

   > **Note**
   >
   > Alternatively, you can create a new key pair using a third-party tool. For more information, see Create a key pair using a third-party tool and import the public key to Amazon EC2.

2. Add the new key pair to your instance. For more information, see I've lost my private key. How can I connect to my instance?.
3. Connect to your instance using the new key pair.

Error: User key not recognized by server

If you use SSH to connect to your instance

- Use `ssh -vvv` to get triple verbose debugging information while connecting:

```
ssh -vvv -i path/key-pair-name.pem instance-user-
name@ec2-203-0-113-25.compute-1.amazonaws.eu
```

The following sample output demonstrates what you might see if you were trying to connect to your instance with a key that was not recognized by the server:

```
open/ANT/myusername/.ssh/known_hosts).
debug2: bits set: 504/1024
debug1: ssh_rsa_verify: signature correct

debug1: Authentications that can continue: publickey
debug2: we did not send a packet, disable method
debug1: No more authentication methods to try.
Permission denied (publickey).
```

If you use PuTTY to connect to your instance

- Verify that your private key (.pem) file has been converted to the format recognized by PuTTY (.ppk). For more information about converting your private key, see Connect to your Linux instance using PuTTY.

> **Note**
>
> In PuTTYgen, load your private key file and select **Save Private Key** rather than **Generate**.

- Verify that you are connecting with the appropriate username for your AMI. Enter the username in the **Host name** box in the **PuTTY Configuration** window.

AMI used to launch instance	Default username
Amazon Linux	`ec2-user`
CentOS	`centos` or `ec2-user`
Debian	`admin`
Fedora	`fedora` or `ec2-user`
FreeBSD	`ec2-user`
RHEL	`ec2-user` or `root`
SUSE	`ec2-user` or `root`
Ubuntu	`ubuntu`
Oracle	`ec2-user`
Bitnami	`bitnami`
Rocky Linux	`rocky`
Other	Check with the AMI provider

- Verify that you have an inbound security group rule to allow inbound traffic to the appropriate port. For more information, see Rules to connect to instances from your computer.

Error: Permission denied or connection closed by [instance] port 22

If you connect to your instance using SSH and get any of the following errors, `Host key not found in [directory]`, `Permission denied (publickey)`, `Authentication failed, permission denied`, or `Connection closed by [instance] port 22`, verify that you are connecting with the appropriate username for your AMI *and* that you have specified the proper private key (`.pem`) file for your instance.

The appropriate usernames are as follows:

AMI used to launch instance	Default username
Amazon Linux	`ec2-user`
CentOS	`centos` or `ec2-user`
Debian	`admin`
Fedora	`fedora` or `ec2-user`
FreeBSD	`ec2-user`
RHEL	`ec2-user` or `root`
SUSE	`ec2-user` or `root`
Ubuntu	`ubuntu`
Oracle	`ec2-user`
Bitnami	`bitnami`
Rocky Linux	`rocky`
Other	Check with the AMI provider

For example, to use an SSH client to connect to an Amazon Linux instance, use the following command:

```
ssh -i /path/key-pair-name.pem instance-user-
name@ec2-203-0-113-25.compute-1.amazonaws.eu
```

Confirm that you are using the private key file that corresponds to the key pair that you selected when you launched the instance.

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances** and then select your instance.
3. On the **Details** tab, under **Instance details**, verify the value of **Key pair name**.
4. If you did not specify a key pair when you launched the instance, you can terminate the instance and launch a new instance, ensuring that you specify a key pair. If this is an instance that you have been using but you no longer have the `.pem` file for your key pair, you can replace the key pair with a new one. For more information, see I've lost my private key. How can I connect to my instance?.

If you generated your own key pair, ensure that your key generator is set up to create RSA keys. DSA keys are not accepted.

If you get a `Permission denied (publickey)` error and none of the above applies (for example, you were able to connect previously), the permissions on the home directory of your instance may have been changed. Permissions for /home/*instance-user-name*/.ssh/authorized_keys must be limited to the owner only.

To verify the permissions on your instance

1. Stop your instance and detach the root volume. For more information, see Stop and start Amazon EC2 instances.
2. Launch a temporary instance in the same Availability Zone as your current instance (use a similar or the same AMI as you used for your current instance), and attach the root volume to the temporary instance.
3. Connect to the temporary instance, create a mount point, and mount the volume that you attached.
4. From the temporary instance, check the permissions of the /home/*instance-user-name*/ directory of the attached volume. If necessary, adjust the permissions as follows:

```
[ec2-user ~]$ chmod 600 mount_point/home/instance-user-name/.ssh/authorized_keys
```

```
[ec2-user ~]$ chmod 700 mount_point/home/instance-user-name/.ssh
```

```
[ec2-user ~]$ chmod 700 mount_point/home/instance-user-name
```

5. Unmount the volume, detach it from the temporary instance, and re-attach it to the original instance. Ensure that you specify the correct device name for the root volume; for example, `/dev/xvda`.
6. Start your instance. If you no longer require the temporary instance, you can terminate it.

Error: Unprotected private key file

Your private key file must be protected from read and write operations from any other users. If your private key can be read or written to by anyone but you, then SSH ignores your key and you see the following warning message below.

```
@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@
@         WARNING: UNPROTECTED PRIVATE KEY FILE!          @
@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@
Permissions 0777 for '.ssh/my_private_key.pem' are too open.
It is required that your private key files are NOT accessible by others.
This private key will be ignored.
bad permissions: ignore key: .ssh/my_private_key.pem
Permission denied (publickey).
```

If you see a similar message when you try to log in to your instance, examine the first line of the error message to verify that you are using the correct public key for your instance. The above example uses the private key `.ssh/my_private_key.pem` with file permissions of `0777`, which allow anyone to read or write to this file. This permission level is very insecure, and so SSH ignores this key.

If you are connecting from macOS or Linux, run the following command to fix this error, substituting the path for your private key file.

```
[ec2-user ~]$ chmod 0400 .ssh/my_private_key.pem
```

If you are connecting to a Linux instance from Windows, perform the following steps on your local computer.

1. Navigate to your .pem file.
2. Open the context (right-click) menu for the .pem file and select **Properties**.
3. Choose the **Security** tab.
4. Select **Advanced**.
5. Verify that you are the owner of the file. If not, change the owner to your username.
6. Select **Disable inheritance** and **Remove all inherited permissions from this object**.
7. Select **Add**, **Select a principal**, enter your username, and select **OK**.
8. From the **Permission Entry** window, grant **Read** permissions and select **OK**.
9. Click **Apply** to ensure all settings are saved.
10. Select **OK** to close the **Advanced Security Settings** window.
11. Select **OK** to close the **Properties** window.
12. You should be able to connect to your Linux instance from Windows using SSH.

From a Windows command prompt, run the following commands.

1. From the command prompt, navigate to the file path location of your .pem file.
2. Run the following command to reset and remove explicit permissions:

```
icacls.exe $path /reset
```

3. Run the following command to grant Read permissions to the current user:

```
icacls.exe $path /GRANT:R "$($env:USERNAME):(R)"
```

4. Run the following command to disable inheritance and remove inherited permissions.

```
icacls.exe $path /inheritance:r
```

5. You should be able to connect to your Linux instance from Windows using SSH.

Error: Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"

If you use a third-party tool, such as **ssh-keygen**, to create an RSA key pair, it generates the private key in the OpenSSH key format. When you connect to your instance, if you use the private key in

the OpenSSH format to decrypt the password, you'll get the error `Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"`.

To resolve the error, the private key must be in the PEM format. Use the following command to create the private key in the PEM format:

```
ssh-keygen -m PEM
```

Error: Host key verification failed

This error occurs if there is a mismatch between the host key stored on the instance in the `known_hosts` file and on the client. For example, a mismatch can occur if you connect to an instance using one public IP address, and then try to connect to it again using a different public IP address. This can happen after you add or remove an Elastic IP address, as doing so changes the public IP address of an instance.

To resolve this error, start by confirming that there was an expected change to the host key or the network configuration of the instance. Before you connect to the instance, you might also want to verify the host fingerprint. After you connect to the instance, you can remove the old host key from the `known_hosts` file. For instructions, refer to the documentation for the Linux distribution in use on your instance.

Error: Server refused our key *or* No supported authentication methods available

If you use PuTTY to connect to your instance and get either of the following errors, Error: Server refused our key or Error: No supported authentication methods available, verify that you are connecting with the appropriate username for your AMI. Type the username in **User name** in the **PuTTY Configuration** window.

The appropriate usernames are as follows:

AMI used to launch instance	Default username
Amazon Linux	`ec2-user`
CentOS	`centos` or `ec2-user`

AMI used to launch instance	Default username
Debian	`admin`
Fedora	`fedora` or `ec2-user`
FreeBSD	`ec2-user`
RHEL	`ec2-user` or `root`
SUSE	`ec2-user` or `root`
Ubuntu	`ubuntu`
Oracle	`ec2-user`
Bitnami	`bitnami`
Rocky Linux	`rocky`
Other	Check with the AMI provider

You should also verify that:

- You are using the latest version of PuTTY. For more information, see the PuTTY web page.
- Your private key (.pem) file has been correctly converted to the format recognized by PuTTY (.ppk). For more information about converting your private key, see Connect to your Linux instance using PuTTY.

Cannot ping instance

The `ping` command is a type of ICMP traffic — if you are unable to ping your instance, ensure that your inbound security group rules allow ICMP traffic for the `Echo Request` message from all sources, or from the computer or instance from which you are issuing the command.

If you are unable to issue a `ping` command from your instance, ensure that your outbound security group rules allow ICMP traffic for the `Echo Request` message to all destinations, or to the host that you are attempting to ping.

Ping commands can also be blocked by a firewall or time out due to network latency or hardware issues. You should consult your local network or system administrator for help with further troubleshooting.

Error: Server unexpectedly closed network connection

If you are connecting to your instance with PuTTY and you receive the error "Server unexpectedly closed network connection," verify that you have enabled keepalives on the Connection page of the PuTTY Configuration to avoid being disconnected. Some servers disconnect clients when they do not receive any data within a specified period of time. Set the Seconds between keepalives to 59 seconds.

If you still experience issues after enabling keepalives, try to disable Nagle's algorithm on the Connection page of the PuTTY Configuration.

Error: Host key validation failed for EC2 Instance Connect

If you rotate your instance host keys, the new host keys are not automatically uploaded to the AWS trusted host keys database. This causes host key validation to fail when you try to connect to your instance using the EC2 Instance Connect browser-based client, and you're unable to connect to your instance.

To resolve the error, you must run the `eic_harvest_hostkeys` script on your instance, which uploads your new host key to EC2 Instance Connect. The script is located at `/opt/aws/bin/` on Amazon Linux 2 instances, and at `/usr/share/ec2-instance-connect/` on Ubuntu instances.

Amazon Linux 2

To resolve the host key validation failed error on an Amazon Linux 2 instance

1. Connect to your instance using SSH.

   You can connect by using the EC2 Instance Connect CLI or by using the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For Amazon Linux 2, the default username is `ec2-user`.

   For example, if your instance was launched using Amazon Linux 2, your instance's public DNS name is `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-
west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see Connect to your Linux instance using an SSH client.

2. Navigate to the following folder.

```
[ec2-user ~]$ cd /opt/aws/bin/
```

3. Run the following command on your instance.

```
[ec2-user ~]$ ./eic_harvest_hostkeys
```

Note that a successful call results in no output.

You can now use the EC2 Instance Connect browser-based client to connect to your instance.

Ubuntu

To resolve the host key validation failed error on an Ubuntu instance

1. Connect to your instance using SSH.

You can connect by using the EC2 Instance Connect CLI or by using the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For Ubuntu, the default username is `ubuntu`.

For example, if your instance was launched using Ubuntu, your instance's public DNS name is `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-
west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see Connect to your Linux instance using an SSH client.

2. Navigate to the following folder.

```
[ec2-user ~]$ cd /usr/share/ec2-instance-connect/
```

3. Run the following command on your instance.

```
[ec2-user ~]$ ./eic_harvest_hostkeys
```

Note that a successful call results in no output.

You can now use the EC2 Instance Connect browser-based client to connect to your instance.

Can't connect to Ubuntu instance using EC2 Instance Connect

If you use EC2 Instance Connect to connect to your Ubuntu instance and you get an error when attempting to connect, you can use the following information to try to fix the issue.

Possible cause

The `ec2-instance-connect` package on the instance is not the latest version.

Solution

Update the `ec2-instance-connect` package on the instance to the latest version, as follows:

1. Connect to your instance using a method other than EC2 Instance Connect.
2. Run the following command on your instance to update the `ec2-instance-connect` package to the latest version.

```
apt update && apt upgrade
```

I've lost my private key. How can I connect to my instance?

If you lose the private key for an EBS-backed instance, you can regain access to your instance. You must stop the instance, detach its root volume and attach it to another instance as a data volume, modify the `authorized_keys` file with a new public key, move the volume back to the original instance, and restart the instance. For more information about launching, connecting to, and stopping instances, see Amazon EC2 instance state changes.

This procedure is only supported for instances with EBS root volumes. If the instance has an instance store root volume, you cannot use this procedure to regain access to your instance; you must have the private key to connect to the instance. To determine the root volume type of your instance, open the Amazon EC2 console, choose **Instances**, select the instance, choose the **Storage** tab, and in the **Root device details** section, check the value of **Root device type**.

The value is either `EBS` or `INSTANCE-STORE`.

In addition to the following steps, there are other ways to connect to your Linux instance if you lose your private key. For more information, see How can I connect to my Amazon EC2 instance if I lost my SSH key pair after its initial launch?

Steps for connecting to an EBS-backed instance with a different key pair

- Step 1: Create a new key pair
- Step 2: Get information about the original instance and its root volume
- Step 3: Stop the original instance
- Step 4: Launch a temporary instance
- Step 5: Detach the root volume from the original instance and attach it to the temporary instance
- Step 6: Add the new public key to authorized_keys on the original volume mounted to the temporary instance
- Step 7: Unmount and detach the original volume from the temporary instance, and reattach it to the original instance
- Step 8: Connect to the original instance using the new key pair
- Step 9: Clean up

Step 1: Create a new key pair

Create a new key pair using either the Amazon EC2 console or a third-party tool. If you want to name your new key pair exactly the same as the lost private key, you must first delete the existing key pair. For information about creating a new key pair, see Create a key pair using Amazon EC2 or Create a key pair using a third-party tool and import the public key to Amazon EC2.

Step 2: Get information about the original instance and its root volume

Make note of the following information because you'll need it to complete this procedure.

To get information about your original instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. Choose **Instances** in the navigation pane, and then select the instance that you'd like to connect to. (We'll refer to this as the *original* instance.)
3. On the **Details** tab, make note of the instance ID and AMI ID.
4. On the **Networking** tab, make note of the Availability Zone.
5. On the **Storage** tab, under **Root device name**, make note of the device name for the root volume (for example, `/dev/xvda`). Then, under **Block devices**, find this device name and make note of the volume ID (for example, vol-0a1234b5678c910de).

Step 3: Stop the original instance

Choose **Instance state**, **Stop instance**. If this option is disabled, either the instance is already stopped or its root volume is an instance store volume.

> **Warning**
>
> When you stop an instance, the data on instance store volumes is lost. To preserve this data, back it up to persistent storage.

Step 4: Launch a temporary instance

To launch a temporary instance

1. In the navigation pane, choose **Instances**, and then choose **Launch instances**.
2. In the **Name and tags** section, for **Name**, enter **Temporary**.
3. In the **Application and OS Images** section, select the same AMI that you used to launch the original instance. If this AMI is unavailable, you can create an AMI that you can use from the stopped instance. For more information, see Create an Amazon EBS-backed AMI.
4. In the **Instance type** section, keep the default instance type.
5. In the **Key pair** section, for **Key pair name**, select the existing key pair to use or create a new one.
6. In the **Network settings** section, choose **Edit**, and then for **Subnet**, select a subnet in the same Availability Zone as the original instance.

7. In the **Summary** panel, choose **Launch**.

Step 5: Detach the root volume from the original instance and attach it to the temporary instance

1. In the navigation pane, choose **Volumes** and select the root volume for the original instance (you made note of its volume ID in a previous step). Choose **Actions**, **Detach volume**, and then choose **Detach**. Wait for the state of the volume to become `available`. (You might need to choose the Refresh icon.)
2. With the volume still selected, choose **Actions**, and then choose **Attach volume**. Select the instance ID of the temporary instance, make note of the device name specified under **Device name** (for example, `/dev/sdf`), and then choose **Attach volume**.

> **Note**
>
> If you launched your original instance from an AWS Marketplace AMI and your volume contains AWS Marketplace codes, you must first stop the temporary instance before you can attach the volume.

Step 6: Add the new public key to `authorized_keys` on the original volume mounted to the temporary instance

1. Connect to the temporary instance.
2. From the temporary instance, mount the volume that you attached to the instance so that you can access its file system. For example, if the device name is `/dev/sdf`, use the following commands to mount the volume as `/mnt/tempvol`.

> **Note**
>
> The device name might appear differently on your instance. For example, devices mounted as `/dev/sdf` might show up as `/dev/xvdf` on the instance. Some versions of Red Hat (or its variants, such as CentOS) might even increment the trailing letter by 4 characters, where `/dev/sd`*`f`* becomes `/dev/xvd`*`k`*.

a. Use the **lsblk** command to determine if the volume is partitioned.

```
[ec2-user ~]$ lsblk
NAME    MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda    202:0    0    8G  0 disk
##xvda1 202:1    0    8G  0 part /
xvdf    202:80   0  101G  0 disk
##xvdf1 202:81   0  101G  0 part
xvdg    202:96   0   30G  0 disk
```

In the preceding example, `/dev/xvda` and `/dev/xvdf` are partitioned volumes, and `/dev/xvdg` is not. If your volume is partitioned, you mount the partition (`/dev/xvdf1`) instead of the raw device (`/dev/xvdf`) in the next steps.

b. Create a temporary directory to mount the volume.

```
[ec2-user ~]$ sudo mkdir /mnt/tempvol
```

c. Mount the volume (or partition) at the temporary mount point, using the volume name or device name that you identified earlier. The required command depends on your operating system's file system. Note that the device name might appear differently on your instance. See the note in Step 6 for more information.

- Amazon Linux, Ubuntu, and Debian

```
[ec2-user ~]$ sudo mount /dev/xvdf1 /mnt/tempvol
```

- Amazon Linux 2, CentOS, SUSE Linux 12, and RHEL 7.x

```
[ec2-user ~]$ sudo mount -o nouuid /dev/xvdf1 /mnt/tempvol
```

Note

If you get an error stating that the file system is corrupt, run the following command to use the **fsck** utility to check the file system and repair any issues:

```
[ec2-user ~]$ sudo fsck /dev/xvdf1
```

3. From the temporary instance, use the following command to update `authorized_keys` on the mounted volume with the new public key from the `authorized_keys` for the temporary instance.

> **Important**
>
> The following examples use the Amazon Linux username `ec2-user`. You might need to substitute a different username, such as `ubuntu` for Ubuntu instances.

```
[ec2-user ~]$ cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh/
authorized_keys
```

If this copy succeeded, you can go to the next step.

(Optional) Otherwise, if you don't have permission to edit files in `/mnt/tempvol`, you must update the file using **sudo** and then check the permissions on the file to verify that you are able to log into the original instance. Use the following command to check the permissions on the file.

```
[ec2-user ~]$ sudo ls -l /mnt/tempvol/home/ec2-user/.ssh
total 4
-rw------- 1 222 500 398 Sep 13 22:54 authorized_keys
```

In this example output, *222* is the user ID and *500* is the group ID. Next, use **sudo** to re-run the copy command that failed.

```
[ec2-user ~]$ sudo cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh/
authorized_keys
```

Run the following command again to determine whether the permissions changed.

```
[ec2-user ~]$ sudo ls -l /mnt/tempvol/home/ec2-user/.ssh
```

If the user ID and group ID have changed, use the following command to restore them.

```
[ec2-user ~]$ sudo chown 222:500 /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
```

Step 7: Unmount and detach the original volume from the temporary instance, and reattach it to the original instance

1. From the temporary instance, unmount the volume that you attached so that you can reattach it to the original instance. For example, use the following command to unmount the volume at `/mnt/tempvol`.

   ```
   [ec2-user ~]$ sudo umount /mnt/tempvol
   ```

2. Detach the volume from the temporary instance (you unmounted it in the previous step): From the Amazon EC2 console, choose **Volumes** in the navigation pane, select the root volume for the original instance (you made note of the volume ID in a previous step), choose **Actions**, **Detach volume**, and then choose **Detach**. Wait for the state of the volume to become `available`. (You might need to choose the Refresh icon.)
3. Reattach the volume to the original instance: With the volume still selected, choose **Actions**, **Attach volume**. Select the instance ID of the original instance, specify the device name that you noted earlier in Step 2 for the original root volume attachment (`/dev/sda1` or `/dev/xvda`), and then choose **Attach volume**.

   Important

   If you don't specify the same device name as the original attachment, you cannot start the original instance. Amazon EC2 expects the root volume at `sda1` or `/dev/xvda`.

Step 8: Connect to the original instance using the new key pair

Select the original instance, choose **Instance state**, **Start instance**. After the instance enters the `running` state, you can connect to it using the private key file for your new key pair.

Note

If the name of your new key pair and corresponding private key file is different from the name of the original key pair, ensure that you specify the name of the new private key file when you connect to your instance.

Step 9: Clean up

(Optional) You can terminate the temporary instance if you have no further use for it. Select the temporary instance, and choose **Instance state**, **Terminate (delete) instance**.

Troubleshoot Amazon EC2 Linux instances with failed status checks

The following information can help you troubleshoot issues if your Linux instance fails a status check. First determine whether your applications are exhibiting any problems. If you verify that the instance is not running your applications as expected, review the status check information and the system logs.

For examples of problems that can cause status checks to fail, see Status checks for Amazon EC2 instances.

Contents

- Review status check information
- Retrieve the system logs
- Troubleshoot system log errors for Linux instances
- Out of memory: kill process
- ERROR: mmu_update failed (Memory management update failed)
- I/O error (block device failure)
- I/O ERROR: neither local nor remote disk (Broken distributed block device)
- request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions)
- "FATAL: kernel too old" and "fsck: No such file or directory while trying to open /dev" (Kernel and AMI mismatch)
- "FATAL: Could not load /lib/modules" or "BusyBox" (Missing kernel modules)
- ERROR Invalid kernel (EC2 incompatible kernel)
- fsck: No such file or directory while trying to open... (File system not found)
- General error mounting filesystems (failed mount)
- VFS: Unable to mount root fs on unknown-block (Root filesystem mismatch)

- Error: Unable to determine major/minor number of root device... (Root file system/device mismatch)
- XENBUS: Device with no driver...
- ... days without being checked, check forced (File system check required)
- fsck died with exit status... (Missing device)
- GRUB prompt (grubdom>)
- Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address)
- Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration)
- XENBUS: Timeout connecting to devices (Xenbus timeout)

Review status check information

To investigate impaired instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. Select the **Status and alarms** tab to see the individual results for all **System status checks**, **Instance status checks**, and **Attached EBS status checks**.

If a status check has failed, you can try one of the following options:

- Create an alarm to recover the instance in response to the failed status check. For more information, see Create alarms that stop, terminate, reboot, or recover an instance.
- (Instance status checks) If you changed the instance type to a Nitro-based instance, status checks fail if you migrated from an instance that does not have the required ENA and NVMe drivers. For more information, see Compatibility for changing the instance type.
- For an instance with an EBS root volume, stop and restart the instance. For more information, see Stop and start Amazon EC2 instances.
- For an instance with an instance store root volume, terminate the instance and launch a replacement instance. For more information, see Terminate Amazon EC2 instances.
- Wait for Amazon EC2 to resolve the issue.

- Contact Support or post your issue to AWS re:Post.
- If your instance is in an Auto Scaling group:
  - (System status checks and instance status checks) By default, Amazon EC2 Auto Scaling automatically launches a replacement instance. For more information, see Health checks for instances in an Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.
  - (Attached EBS status checks) You must configure Amazon EC2 Auto Scaling to automatically launch a replacement instance. For more information, see Monitor and replace Auto Scaling instances with impaired Amazon EBS volumes in the *Amazon EC2 Auto Scaling User Guide*.
- Retrieve the system log and look for errors. For more information, see Retrieve the system logs.

Retrieve the system logs

If an instance status check fails, you can reboot the instance and retrieve the system logs. The logs may reveal an error that can help you troubleshoot the issue. Rebooting clears unnecessary information from the logs.

To reboot an instance and retrieve the system log

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**, and select your instance.
3. Choose **Instance state**, **Reboot instance**. It might take a few minutes for your instance to reboot.
4. Verify that the problem still exists; in some cases, rebooting may resolve the problem.
5. When the instance is in the `running` state, choose **Actions**, **Monitor and troubleshoot**, **Get system log**.
6. Review the log that appears on the screen, and use the list of known system log error statements below to troubleshoot your issue.
7. If your issue is not resolved, you can post your issue to AWS re:Post.

Troubleshoot system log errors for Linux instances

For Linux instances that have failed an instance status check, such as the instance reachability check, verify that you followed the steps above to retrieve the system log. The following list contains some common system log errors and suggested actions you can take to resolve the issue for each error.

Memory Errors

- Out of memory: kill process
- ERROR: mmu_update failed (Memory management update failed)

Device Errors

- I/O error (block device failure)
- I/O ERROR: neither local nor remote disk (Broken distributed block device)

Kernel Errors

- request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions)
- "FATAL: kernel too old" and "fsck: No such file or directory while trying to open /dev" (Kernel and AMI mismatch)
- "FATAL: Could not load /lib/modules" or "BusyBox" (Missing kernel modules)
- ERROR Invalid kernel (EC2 incompatible kernel)

File System Errors

- fsck: No such file or directory while trying to open... (File system not found)
- General error mounting filesystems (failed mount)
- VFS: Unable to mount root fs on unknown-block (Root filesystem mismatch)
- Error: Unable to determine major/minor number of root device... (Root file system/device mismatch)
- XENBUS: Device with no driver...
- ... days without being checked, check forced (File system check required)
- fsck died with exit status... (Missing device)

Operating System Errors

- GRUB prompt (grubdom>)

- Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address)
- Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration)
- XENBUS: Timeout connecting to devices (Xenbus timeout)

Out of memory: kill process

An out-of-memory error is indicated by a system log entry similar to the one shown below.

```
[115879.769795] Out of memory: kill process 20273 (httpd) score 1285879
or a child
[115879.769795] Killed process 1917 (php-cgi) vsz:467184kB, anon-
rss:101196kB, file-rss:204kB
```

Potential cause

Exhausted memory

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Do one of the following: • Stop the instance, and modify the instance to use a different instance type, and start the instance again. For example, a larger or a memory-optimized instance type. • Reboot the instance to return it to a non-impaired status. The problem will probably occur again unless you change the instance type.
Instance store-backed	Do one of the following: • Terminate the instance and launch a new instance, specifying a different instance

For this instance type	Do this
	type. For example, a larger or a memory-optimized instance type. • Reboot the instance to return it to an unimpaired status. The problem will probably occur again unless you change the instance type.

ERROR: mmu_update failed (Memory management update failed)

Memory management update failures are indicated by a system log entry similar to the following:

```
...
Press `ESC' to enter the menu... 0   [H[J  Booting 'Amazon Linux 2011.09
 (2.6.35.14-95.38.amzn1.i686)'

root (hd0)

 Filesystem type is ext2fs, using whole disk

kernel /boot/vmlinuz-2.6.35.14-95.38.amzn1.i686 root=LABEL=/ console=hvc0 LANG=

en_US.UTF-8 KEYTABLE=us

initrd /boot/initramfs-2.6.35.14-95.38.amzn1.i686.img

ERROR: mmu_update failed with rc=-22
```

Potential cause

Issue with Amazon Linux

Suggested action

Post your issue to AWS re:Post or contact Support.

I/O error (block device failure)

An input/output error is indicated by a system log entry similar to the following example:

```
[9943662.053217] end_request: I/O error, dev sde, sector 52428288
[9943664.191262] end_request: I/O error, dev sde, sector 52428168
[9943664.191285] Buffer I/O error on device md0, logical block 209713024
[9943664.191297] Buffer I/O error on device md0, logical block 209713025
[9943664.191304] Buffer I/O error on device md0, logical block 209713026
[9943664.191310] Buffer I/O error on device md0, logical block 209713027
[9943664.191317] Buffer I/O error on device md0, logical block 209713028
[9943664.191324] Buffer I/O error on device md0, logical block 209713029
[9943664.191332] Buffer I/O error on device md0, logical block 209713030
[9943664.191339] Buffer I/O error on device md0, logical block 209713031
[9943664.191581] end_request: I/O error, dev sde, sector 52428280
[9943664.191590] Buffer I/O error on device md0, logical block 209713136
[9943664.191597] Buffer I/O error on device md0, logical block 209713137
[9943664.191767] end_request: I/O error, dev sde, sector 52428288
[9943664.191970] end_request: I/O error, dev sde, sector 52428288
[9943664.192143] end_request: I/O error, dev sde, sector 52428288
[9943664.192949] end_request: I/O error, dev sde, sector 52428288
[9943664.193112] end_request: I/O error, dev sde, sector 52428288
[9943664.193266] end_request: I/O error, dev sde, sector 52428288
...
```

Potential causes

Instance type	Potential cause
Amazon EBS-backed	A failed Amazon EBS volume
Instance store-backed	A failed physical drive

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance.

For this instance type	Do this
	2. Detach the volume. 3. Attempt to recover the volume. **Note** It's good practice to snapshot your Amazon EBS volumes often. This dramatically decreases the risk of data loss as a result of failure. 4. Re-attach the volume to the instance. 5. Start the instance.
Instance store-backed	Terminate the instance and launch a new instance. **Note** Data cannot be recovered. Recover from backups. **Note** It's a good practice to use either Amazon S3 or Amazon EBS for backups. Instance store volumes are directly tied to single host and single disk failures.

I/O ERROR: neither local nor remote disk (Broken distributed block device)

An input/output error on the device is indicated by a system log entry similar to the following example:

```
...
block drbd1: Local IO failed in request_timer_fn. Detaching...

Aborting journal on device drbd1-8.

block drbd1: IO ERROR: neither local nor remote disk

Buffer I/O error on device drbd1, logical block 557056

lost page write due to I/O error on drbd1

JBD2: I/O error detected when updating journal superblock for drbd1-8.
```

Potential causes

Instance type	Potential cause
Amazon EBS-backed	A failed Amazon EBS volume
Instance store-backed	A failed physical drive

Suggested action

Terminate the instance and launch a new instance.

For an Amazon EBS-backed instance you can recover data from a recent snapshot by creating an image from it. Any data added after the snapshot cannot be recovered.

request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions)

This condition is indicated by a system log similar to the one shown below. Using an unstable or old Linux kernel (for example, 2.6.16-xenU) can cause an interminable loop condition at startup.

```
Linux version 2.6.16-xenU (builder@xenbat.amazonsa) (gcc version 4.0.1
20050727 (Red Hat 4.0.1-5)) #1 SMP Mon May 28 03:41:49 SAST 2007

BIOS-provided physical RAM map:

 Xen: 0000000000000000 - 0000000026700000 (usable)

0MB HIGHMEM available.
...

request_module: runaway loop modprobe binfmt-464c

request_module: runaway loop modprobe binfmt-464c

request_module: runaway loop modprobe binfmt-464c

request_module: runaway loop modprobe binfmt-464c

request_module: runaway loop modprobe binfmt-464c
```

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use a newer kernel, either GRUB-based or static, using one of the following options: Option 1: Terminate the instance and launch a new instance, specifying the `-kernel` and `-ramdisk` parameters. Option 2: 1. Stop the instance. 2. Modify the kernel and ramdisk attributes to use a newer kernel. 3. Start the instance.

For this instance type	Do this
Instance store-backed	Terminate the instance and launch a new instance, specifying the `-kernel` and `-ramdisk` parameters.

"FATAL: kernel too old" and "fsck: No such file or directory while trying to open /dev" (Kernel and AMI mismatch)

This condition is indicated by a system log similar to the one shown below.

```
Linux version 2.6.16.33-xenU (root@dom0-0-50-45-1-a4-ee.z-2.aes0.internal)
(gcc version 4.1.1 20070105 (Red Hat 4.1.1-52)) #2 SMP Wed Aug 15 17:27:36 SAST 2007
...
FATAL: kernel too old
Kernel panic - not syncing: Attempted to kill init!
```

Potential causes

Incompatible kernel and userland

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance. 2. Modify the configuration to use a newer kernel. 3. Start the instance.
Instance store-backed	Use the following procedure: 1. Create an AMI that uses a newer kernel. 2. Terminate the instance.

For this instance type	Do this
	3. Start a new instance from the AMI you created.

"FATAL: Could not load /lib/modules" or "BusyBox" (Missing kernel modules)

This condition is indicated by a system log similar to the one shown below.

```
[    0.370415] Freeing unused kernel memory: 1716k freed
Loading, please wait...
WARNING: Couldn't open directory /lib/modules/2.6.34-4-virtual: No such file or
 directory
FATAL: Could not open /lib/modules/2.6.34-4-virtual/modules.dep.temp for writing: No
 such file or directory
FATAL: Could not load /lib/modules/2.6.34-4-virtual/modules.dep: No such file or
 directory
Couldn't get a file descriptor referring to the console
Begin: Loading essential drivers... ...
FATAL: Could not load /lib/modules/2.6.34-4-virtual/modules.dep: No such file or
 directory
FATAL: Could not load /lib/modules/2.6.34-4-virtual/modules.dep: No such file or
 directory
Done.
Begin: Running /scripts/init-premount ...
Done.

Begin: Waiting for root file system... ...
Done.
Gave up waiting for root device.  Common problems:
 - Boot args (cat /proc/cmdline)
   - Check rootdelay= (did the system wait long enough?)
   - Check root= (did the system wait for the right device?)
 - Missing modules (cat /proc/modules; ls /dev)
FATAL: Could not load /lib/modules/2.6.34-4-virtual/modules.dep: No such file or
 directory
FATAL: Could not load /lib/modules/2.6.34-4-virtual/modules.dep: No such file or
 directory
```

```
ALERT! /dev/sda1 does not exist. Dropping to a shell!

BusyBox v1.13.3 (Ubuntu 1:1.13.3-1ubuntu5) built-in shell (ash)
Enter 'help' for a list of built-in commands.

(initramfs)
```

Potential causes

One or more of the following conditions can cause this problem:

- Missing ramdisk
- Missing correct modules from ramdisk
- Amazon EBS root volume not correctly attached as `/dev/sda1`

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Select corrected ramdisk for the Amazon EBS volume. 2. Stop the instance. 3. Detach the volume and repair it. 4. Attach the volume to the instance. 5. Start the instance. 6. Modify the AMI to use the corrected ramdisk.
Instance store-backed	Use the following procedure: 1. Terminate the instance and launch a new instance with the correct ramdisk. 2. Create a new AMI with the correct ramdisk.

ERROR Invalid kernel (EC2 incompatible kernel)

This condition is indicated by a system log similar to the one shown below.

```
...
root (hd0)

 Filesystem type is ext2fs, using whole disk

kernel /vmlinuz root=/dev/sda1 ro

initrd /initrd.img

ERROR Invalid kernel: elf_xen_note_check: ERROR: Will only load images
built for the generic loader or Linux images
xc_dom_parse_image returned -1

Error 9: Unknown boot failure

  Booting 'Fallback'

root (hd0)

 Filesystem type is ext2fs, using whole disk

kernel /vmlinuz.old root=/dev/sda1 ro

Error 15: File not found
```

Potential causes

One or both of the following conditions can cause this problem:

- Supplied kernel is not supported by GRUB
- Fallback kernel does not exist

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure:

For this instance type	Do this
	1. Stop the instance. 2. Replace with working kernel. 3. Install a fallback kernel. 4. Modify the AMI by correcting the kernel.
Instance store-backed	Use the following procedure: 1. Terminate the instance and launch a new instance with the correct kernel. 2. Create an AMI with the correct kernel. 3. (Optional) Seek technical assistance for data recovery using Support.

fsck: No such file or directory while trying to open... (File system not found)

This condition is indicated by a system log similar to the one shown below.

```
  Welcome to Fedora
  Press 'I' to enter interactive startup.
Setting clock : Wed Oct 26 05:52:05 EDT 2011 [  OK  ]

Starting udev: [  OK  ]

Setting hostname localhost:  [  OK  ]

No devices found
Setting up Logical Volume Management: File descriptor 7 left open
  No volume groups found
[  OK  ]

Checking filesystems
Checking all file systems.
[/sbin/fsck.ext3 (1) -- /] fsck.ext3 -a /dev/sda1
/dev/sda1: clean, 82081/1310720 files, 2141116/2621440 blocks
[/sbin/fsck.ext3 (1) -- /mnt/dbbackups] fsck.ext3 -a /dev/sdh
fsck.ext3: No such file or directory while trying to open /dev/sdh
```

```
/dev/sdh:
The superblock could not be read or does not describe a correct ext2
filesystem.  If the device is valid and it really contains an ext2
filesystem (and not swap or ufs or something else), then the superblock
is corrupt, and you might try running e2fsck with an alternate superblock:
    e2fsck -b 8193 <device>

[FAILED]

*** An error occurred during the file system check.
*** Dropping you to a shell; the system will reboot
*** when you leave the shell.
Give root password for maintenance
(or type Control-D to continue):
```

Potential causes

- A bug exists in ramdisk filesystem definitions /etc/fstab
- Misconfigured filesystem definitions in /etc/fstab
- Missing/failed drive

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance, detach the root volume, repair/modify /etc/fstab the volume, attach the volume to the instance, and start the instance. 2. Fix ramdisk to include modified /etc/fstab (if applicable). 3. Modify the AMI to use a newer ramdisk.

For this instance type	Do this
	The sixth field in the fstab defines availability requirements of the mount – a nonzero value implies that an fsck will be done on that volume and *must* succeed. Using this field can be problematic in Amazon EC2 because a failure typically results in an interactive console prompt that is not currently available in Amazon EC2. Use care with this feature and read the Linux man page for fstab.
Instance store-backed	Use the following procedure: 1. Terminate the instance and launch a new instance. 2. Detach any errant Amazon EBS volumes and the reboot instance. 3. (Optional) Seek technical assistance for data recovery using Support.

General error mounting filesystems (failed mount)

This condition is indicated by a system log similar to the one shown below.

```
Loading xenblk.ko module
xen-vbd: registered block device major 8

Loading ehci-hcd.ko module
Loading ohci-hcd.ko module
Loading uhci-hcd.ko module
USB Universal Host Controller Interface driver v3.0

Loading mbcache.ko module
Loading jbd.ko module
Loading ext3.ko module
Creating root device.
Mounting root filesystem.
kjournald starting.  Commit interval 5 seconds
```

```
EXT3-fs: mounted filesystem with ordered data mode.

Setting up other filesystems.
Setting up new root fs
no fstab.sys, mounting internal defaults
Switching to new root and running init.
unmounting old /dev
unmounting old /proc
unmounting old /sys
mountall:/proc: unable to mount: Device or resource busy
mountall:/proc/self/mountinfo: No such file or directory
mountall: root filesystem isn't mounted
init: mountall main process (221) terminated with status 1

General error mounting filesystems.
A maintenance shell will now be started.
CONTROL-D will terminate this shell and re-try.
Press enter for maintenance
(or type Control-D to continue):
```

Potential causes

Instance type	Potential cause
Amazon EBS-backed	• Detached or failed Amazon EBS volume. • Corrupted filesystem. • Mismatched ramdisk and AMI combination (such as Debian ramdisk with a SUSE AMI).
Instance store-backed	• A failed drive. • A corrupted file system. • A mismatched ramdisk and combination (for example, a Debian ramdisk with a SUSE AMI).

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance. 2. Detach the root volume. 3. Attach the root volume to a known working instance. 4. Run filesystem check (fsck -a /dev/...). 5. Fix any errors. 6. Detach the volume from the known working instance. 7. Attach the volume to the stopped instance. 8. Start the instance. 9. Recheck the instance status.
Instance store-backed	Try one of the following: • Start a new instance. • (Optional) Seek technical assistance for data recovery using Support.

VFS: Unable to mount root fs on unknown-block (Root filesystem mismatch)

This condition is indicated by a system log similar to the one shown below.

```
Linux version 2.6.16-xenU (builder@xenbat.amazonsa) (gcc version 4.0.1
 20050727 (Red Hat 4.0.1-5)) #1 SMP Mon May 28 03:41:49 SAST 2007
...
Kernel command line:  root=/dev/sda1 ro 4
...
Registering block device major 8
...
```

```
Kernel panic - not syncing: VFS: Unable to mount root fs on unknown-block(8,1)
```

Potential causes

Instance type	Potential cause
Amazon EBS-backed	• Device not attached correctly. • Root device not attached at correct device point. • Filesystem not in expected format. • Use of legacy kernel (such as 2.6.16-XenU). • A recent kernel update on your instance (faulty update, or an update bug)
Instance store-backed	Hardware device failure.

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Do one of the following: • Stop and then restart the instance. • Modify root volume to attach at the correct device point, possible /dev/sda1 instead of /dev/sda. • Stop and modify to use modern kernel. • Refer to the documentation for your Linux distribution to check for known update bugs. Change or reinstall the kernel.
Instance store-backed	Terminate the instance and launch a new instance using a modern kernel.

Error: Unable to determine major/minor number of root device... (Root file system/device mismatch)

This condition is indicated by a system log similar to the one shown below.

```
...
XENBUS: Device with no driver: device/vif/0
XENBUS: Device with no driver: device/vbd/2048
drivers/rtc/hctosys.c: unable to open rtc device (rtc0)
Initializing network drop monitor service
Freeing unused kernel memory: 508k freed

done.
:: Running Hook [udev]
:: Triggering uevents...<30>udevd[65]: starting version 173
done.
Waiting 10 seconds for device /dev/xvda1 ...
Root device '/dev/xvda1' doesn't exist. Attempting to create it.
ERROR: Unable to determine major/minor number of root device '/dev/xvda1'.
You are being dropped to a recovery shell
    Type 'exit' to try and continue booting
sh: can't access tty; job control turned off
[ramfs /]#
```

Potential causes

- Missing or incorrectly configured virtual block device driver
- Device enumeration clash (sda versus xvda or sda instead of sda1)
- Incorrect choice of instance kernel

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance. 2. Detach the volume. 3. Fix the device mapping problem.

For this instance type	Do this
	4. Start the instance. 5. Modify the AMI to address device mapping issues.
Instance store-backed	Use the following procedure: 1. Create a new AMI with the appropriate fix (map block device correctly). 2. Terminate the instance and launch a new instance from the AMI you created.

XENBUS: Device with no driver...

This condition is indicated by a system log similar to the one shown below.

```
XENBUS: Device with no driver: device/vbd/2048
drivers/rtc/hctosys.c: unable to open rtc device (rtc0)
Initializing network drop monitor service
Freeing unused kernel memory: 508k freed
:: Starting udevd...
done.
:: Running Hook [udev]
:: Triggering uevents...<30>udevd[65]: starting version 173
done.
Waiting 10 seconds for device /dev/xvda1 ...
Root device '/dev/xvda1' doesn't exist. Attempting to create it.
ERROR: Unable to determine major/minor number of root device '/dev/xvda1'.
You are being dropped to a recovery shell
    Type 'exit' to try and continue booting
sh: can't access tty; job control turned off
[ramfs /]#
```

Potential causes

- Missing or incorrectly configured virtual block device driver
- Device enumeration clash (sda versus xvda)
- Incorrect choice of instance kernel

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance. 2. Detach the volume. 3. Fix the device mapping problem. 4. Start the instance. 5. Modify the AMI to address device mapping issues.
Instance store-backed	Use the following procedure: 1. Create an AMI with the appropriate fix (map block device correctly). 2. Terminate the instance and launch a new instance using the AMI you created.

... days without being checked, check forced (File system check required)

This condition is indicated by a system log similar to the one shown below.

```
...
Checking filesystems
Checking all file systems.
[/sbin/fsck.ext3 (1) -- /] fsck.ext3 -a /dev/sda1
/dev/sda1 has gone 361 days without being checked, check forced
```

Potential causes

Filesystem check time passed; a filesystem check is being forced.

Suggested actions

- Wait until the filesystem check completes. A filesystem check can take a long time depending on the size of the root filesystem.
- Modify your filesystems to remove the filesystem check (fsck) enforcement using tune2fs or tools appropriate for your filesystem.

fsck died with exit status... (Missing device)

This condition is indicated by a system log similar to the one shown below.

```
Cleaning up ifupdown....
Loading kernel modules...done.
...
Activating lvm and md swap...done.
Checking file systems...fsck from util-linux-ng 2.16.2
/sbin/fsck.xfs: /dev/sdh does not exist
fsck died with exit status 8
[31mfailed (code 8).[39;49m
```

Potential causes

- Ramdisk looking for missing drive
- Filesystem consistency check forced
- Drive failed or detached

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Try one or more of the following to resolve the issue: • Stop the instance, attach the volume to an existing running instance. • Manually run consistency checks. • Fix ramdisk to include relevant utilities.

For this instance type	Do this
	• Modify filesystem tuning parameters to remove consistency requirements (not recommended).
Instance store-backed	Try one or more of the following to resolve the issue: • Rebundle ramdisk with correct tooling. • Modify file system tuning parameters to remove consistency requirements (not recommended). • Terminate the instance and launch a new instance. • (Optional) Seek technical assistance for data recovery using Support.

GRUB prompt (grubdom>)

This condition is indicated by a system log similar to the one shown below.

```
    GNU GRUB  version 0.97  (629760K lower / 0K upper memory)

       [ Minimal BASH-like line editing is supported.   For

         the   first   word,  TAB  lists  possible  command

         completions.  Anywhere else TAB lists the possible

         completions of a device/filename. ]

grubdom>
```

Potential causes

Instance type	Potential causes
Amazon EBS-backed	• Missing GRUB configuration file. • Incorrect GRUB image used, expecting GRUB configuration file at a different location. • Unsupported filesystem used to store your GRUB configuration file (for example, converting your root file system to a type that is not supported by an earlier version of GRUB).
Instance store-backed	• Missing GRUB configuration file. • Incorrect GRUB image used, expecting GRUB configuration file at a different location. • Unsupported filesystem used to store your GRUB configuration file (for example, converting your root file system to a type that is not supported by an earlier version of GRUB).

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Option 1: Modify the AMI and relaunch the instance: 1. Modify the source AMI to create a GRUB configuration file at the standard location (/boot/grub/menu.lst). 2. Verify that your version of GRUB supports the underlying file system type and upgrade GRUB if necessary.

For this instance type	Do this
	3. Pick the appropriate GRUB image, (hd0-1st drive or hd00 – 1st drive, 1st partition). 4. Terminate the instance and launch a new one using the AMI that you created. Option 2: Fix the existing instance: 1. Stop the instance. 2. Detach the root filesystem. 3. Attach the root filesystem to a known working instance. 4. Mount filesystem. 5. Create a GRUB configuration file. 6. Verify that your version of GRUB supports the underlying file system type and upgrade GRUB if necessary. 7. Detach filesystem. 8. Attach to the original instance. 9. Modify kernel attribute to use the appropria te GRUB image (1st disk or 1st partition on 1st disk). 10Start the instance.

For this instance type	Do this
Instance store-backed	Option 1: Modify the AMI and relaunch the instance: 1. Create the new AMI with a GRUB configuration file at the standard location (/boot/grub/menu.lst). 2. Pick the appropriate GRUB image, (hd0-1st drive or hd00 – 1st drive, 1st partition). 3. Verify that your version of GRUB supports the underlying file system type and upgrade GRUB if necessary. 4. Terminate the instance and launch a new instance using the AMI you created. Option 2: Terminate the instance and launch a new instance, specifying the correct kernel. **Note** To recover data from the existing instance, contact Support.

Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address)

This condition is indicated by a system log similar to the one shown below.

```
...
Bringing up loopback interface:  [  OK  ]

Bringing up interface eth0:  Device eth0 has different MAC address than expected,
 ignoring.
[FAILED]
```

```
Starting auditd: [  OK  ]
```

Potential causes

There is a hardcoded interface MAC in the AMI configuration

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Do one of the following: • Modify the AMI to remove the hardcoding and relaunch the instance. • Modify the instance to remove the hardcoded MAC address. OR Use the following procedure: 1. Stop the instance. 2. Detach the root volume. 3. Attach the volume to another instance and modify the volume to remove the hardcoded MAC address. 4. Attach the volume to the original instance. 5. Start the instance.
Instance store-backed	Do one of the following: • Modify the instance to remove the hardcoded MAC address. • Terminate the instance and launch a new instance.

Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration)

This condition is indicated by a system log similar to the one shown below.

```
audit(1313445102.626:2): enforcing=1 old_enforcing=0 auid=4294967295
Unable to load SELinux Policy. Machine is in enforcing mode. Halting now.
Kernel panic - not syncing: Attempted to kill init!
```

Potential causes

SELinux has been enabled in error:

- Supplied kernel is not supported by GRUB
- Fallback kernel does not exist

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the failed instance. 2. Detach the failed instance's root volume. 3. Attach the root volume to another running Linux instance (later referred to as a recovery instance). 4. Connect to the recovery instance and mount the failed instance's root volume. 5. Disable SELinux on the mounted root volume. This process varies across Linux distributions; for more information, consult your OS-specific documentation.

For this instance type	Do this
	Note On some systems, you disable SELinux by setting `SELINUX=disabled` in the `/mount_point /etc/sysconfig/selinux` file, where *mount_point* is the location that you mounted the volume on your recovery instance. 6. Unmount and detach the root volume from the recovery instance and reattach it to the original instance. 7. Start the instance.
Instance store-backed	Use the following procedure: 1. Terminate the instance and launch a new instance. 2. (Optional) Seek technical assistance for data recovery using Support.

XENBUS: Timeout connecting to devices (Xenbus timeout)

This condition is indicated by a system log similar to the one shown below.

```
Linux version 2.6.16-xenU (builder@xenbat.amazonsa) (gcc version 4.0.1
20050727 (Red Hat 4.0.1-5)) #1 SMP Mon May 28 03:41:49 SAST 2007
...
XENBUS: Timeout connecting to devices!
...
Kernel panic - not syncing: No init found.  Try passing init= option to kernel.
```

Potential causes

- The block device is not connected to the instance
- This instance is using an old instance kernel

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Do one of the following: • Modify the AMI and instance to use a modern kernel and relaunch the instance. • Reboot the instance.
Instance store-backed	Do one of the following: • Terminate the instance. • Modify the AMI to use a modern kernel, and launch a new instance using this AMI.

Troubleshoot an Amazon EC2 Linux instance booting from wrong volume

In some situations, a volume other than the volume attached to `/dev/xvda` or `/dev/sda` becomes the root volume of a Linux instance. This can happen when you have attached the root volume of another instance, or a volume created from the snapshot of a root volume, to an instance with an existing root volume.

This is due to how the initial ramdisk in Linux works. It chooses the volume defined as `/` in the `/etc/fstab`, and in some distributions, this is determined by the label attached to the volume partition. Specifically, you find that your `/etc/fstab` looks something like the following:

```
LABEL=/ / ext4 defaults,noatime 1 1
tmpfs /dev/shm tmpfs defaults 0 0
devpts /dev/pts devpts gid=5,mode=620 0 0
```

```
sysfs /sys sysfs defaults 0 0
proc /proc proc defaults 0 0
```

If you check the label of both volumes, you see that they both contain the / label:

```
[ec2-user ~]$ sudo e2label /dev/xvda1
/
[ec2-user ~]$ sudo e2label /dev/xvdf1
/
```

In this example, you could end up having /dev/xvdf1 become the root volume that your instance boots to after the initial ramdisk runs, instead of the /dev/xvda1 volume from which you had intended to boot. To solve this, use the same **e2label** command to change the label of the attached volume that you do not want to boot from.

In some cases, specifying a UUID in /etc/fstab can resolve this. However, if both volumes come from the same snapshot, or the secondary is created from a snapshot of the primary volume, they share a UUID.

```
[ec2-user ~]$ sudo blkid
/dev/xvda1: LABEL="/" UUID=73947a77-ddbe-4dc7-bd8f-3fe0bc840778 TYPE="ext4"
 PARTLABEL="Linux" PARTUUID=d55925ee-72c8-41e7-b514-7084e28f7334
/dev/xvdf1: LABEL="old/" UUID=73947a77-ddbe-4dc7-bd8f-3fe0bc840778 TYPE="ext4"
 PARTLABEL="Linux" PARTUUID=d55925ee-72c8-41e7-b514-7084e28f7334
```

To change the label of an attached ext4 volume

1. Use the **e2label** command to change the label of the volume to something other than /.

   ```
   [ec2-user ~]$ sudo e2label /dev/xvdf1 old/
   ```

2. Verify that the volume has the new label.

   ```
   [ec2-user ~]$ sudo e2label /dev/xvdf1
   old/
   ```

To change the label of an attached xfs volume

- Use the **xfs_admin** command to change the label of the volume to something other than /.

```
[ec2-user ~]$ sudo xfs_admin -L old/ /dev/xvdf1
writing all SBs
new label = "old/"
```

After changing the volume label as shown, you should be able to reboot the instance and have the proper volume selected by the initial ramdisk when the instance boots.

> **Important**
>
> If you intend to detach the volume with the new label and return it to another instance to use as the root volume, you must perform the above procedure again and change the volume label back to its original value. Otherwise, the other instance does not boot because the ramdisk is unable to find the volume with the label `/`.

Troubleshoot issues connecting to your Amazon EC2 Windows instance

The following information and common errors can help you troubleshoot issues when connecting to your Windows instance.

Connection issues

- Remote Desktop can't connect to the remote computer
- Error using the macOS RDP client
- RDP displays a black screen instead of the desktop
- Unable to remotely log on to an instance with a user that is not an administrator
- Troubleshooting Remote Desktop issues using AWS Systems Manager
- Enable Remote Desktop on an EC2 instance with remote registry
- I've lost my private key. How can I connect to my Windows instance?

Remote Desktop can't connect to the remote computer

Try the following to resolve issues related to connecting to your instance:

- Verify that you're using the correct public DNS hostname. (In the Amazon EC2 console, select the instance and check **Public DNS (IPv4)** in the details pane.) If your instance is in a VPC and you do not see a public DNS name, you must enable DNS hostnames. For more information, see DNS attributes for your VPC in the *Amazon VPC User Guide*.
- Verify that your instance has a public IPv4 address. If not, you can associate an Elastic IP address with your instance. For more information, see Elastic IP addresses.
- To connect to your instance using an IPv6 address, check that your local computer has an IPv6 address and is configured to use IPv6. For more information, see Configure IPv6 on your instances in the *Amazon VPC User Guide*.
- Verify that your security group has a rule that allows RDP access on port 3389.
- If you copied the password but get the error `Your credentials did not work`, try typing them manually when prompted. It's possible that you missed a character or got an extra white space character when you copied the password.
- Verify that the instance has passed status checks. For more information, see Status checks for Amazon EC2 instances and the section called “Linux instance failed status checks”.
- Verify that the route table for the subnet has a route that sends all traffic destined outside the VPC to the internet gateway for the VPC. For more information, see Creating a custom route table (Internet Gateways) in the *Amazon VPC User Guide*.
- Verify that Windows Firewall, or other firewall software, is not blocking RDP traffic to the instance. We recommend that you disable Windows Firewall and control access to your instance using security group rules. Try one of the following options:
  - Use AWSSupport-TroubleshootRDP to disable the Windows Firewall profiles using SSM Agent. This option requires that the instance is configured for AWS Systems Manager.
  - Use AWSSupport-ExecuteEC2Rescue.
  - Stop the instance, detach the root volume, and attach the volume to a temporary instance as a data volume. Connect to the temporary instance and bring the volume online. Load the registry hive from the data volume. Under `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SharedAccess\Parameters\FirewallPolicyStandardProfile`, set `EnableFirewall` to 0. Unload the registry hive and then bring the volume offline. Detach the volume from the temporary instance and attach it to the original instance as the root volume. Start the original instance.
- Verify that Network Level Authentication is disabled on instances that are not part of an Active Directory domain (use AWSSupport-TroubleshootRDP to disable NLA).

- Verify that the Remote Desktop Service (TermService) Startup Type is Automatic and the service is started (use AWSSupport-TroubleshootRDP to enable and start the RDP service).
- Verify that you are connecting to the correct Remote Desktop Protocol port, which by default is 3389 (use AWSSupport-TroubleshootRDP to read the current RDP port and change it back to 3389).
- Verify that Remote Desktop connections are allowed on your instance (use AWSSupport-TroubleshootRDP to enable Remote Desktop connections).
- Verify that the password has not expired. If the password has expired, you can reset it. For more information, see Reset the Windows administrator password for an Amazon EC2 Windows instance.
- If you attempt to connect using a user that you created on the instance and receive the error The `user cannot connect to the server due to insufficient access privileges`, verify that you granted the user the right to log on locally. For more information, see Grant a Member the Right to Logon Locally.
- If you attempt more than the maximum allowed concurrent RDP sessions, your session is terminated with the message `Your Remote Desktop Services session has ended. Another user connected to the remote computer, so your connection was lost.` By default, you are allowed two concurrent RDP sessions to your instance.

Error using the macOS RDP client

If you are connecting to a Windows Server instance using the Remote Desktop Connection client from the Microsoft website, you may get the following error:

```
Remote Desktop Connection cannot verify the identity of the computer that you want to
 connect to.
```

Download the Microsoft Remote Desktop app from the Mac App Store and use the app to connect to your instance.

RDP displays a black screen instead of the desktop

Try the following to resolve this issue:

- Check the console output for additional information. To get the console output for your instance using the Amazon EC2 console, select the instance, and then choose **Actions**, **Monitor and troubleshoot**, **Get system log**.

- Verify that you are running the latest version of your RDP client.
- Try the default settings for the RDP client.
- If you are using Remote Desktop Connection, try starting it with the `/admin` option as follows.

```
mstsc /v:instance /admin
```

- If the server is running a full-screen application, it might have stopped responding. Use Ctrl +Shift+Esc to start Windows Task Manager, and then close the application.
- If the server is over-used, it might have stopped responding. To monitor the instance using the Amazon EC2 console, select the instance and then select the **Monitoring** tab. If you need to change the instance type to a larger size, see Amazon EC2 instance type changes.

Unable to remotely log on to an instance with a user that is not an administrator

If you are not able to remotely log on to a Windows instance with a user that is not an administrator account, ensure that you have granted the user the right to log on locally. See Grant a user or group the right to log on locally to the domain controllers in the domain.

Troubleshooting Remote Desktop issues using AWS Systems Manager

You can use AWS Systems Manager to troubleshoot issues connecting to your Windows instance using RDP.

AWSSupport-TroubleshootRDP

The AWSSupport-TroubleshootRDP automation document allows the user to check or modify common settings on the target instance that can impact Remote Desktop Protocol (RDP) connections, such as the **RDP Port**, **Network Layer Authentication (NLA)**, and **Windows Firewall** profiles. By default, the document reads and outputs the values of these settings.

The AWSSupport-TroubleshootRDP automation document can be used with EC2 instances, on-premises instances, and virtual machines (VMs) that are enabled for use with AWS Systems Manager (managed instances). In addition, it can also be used with EC2 instances for Windows Server that are *not* enabled for use with Systems Manager. For information about enabling instances for use with AWS Systems Manager, see Managed nodes in the*AWS Systems Manager User Guide*.

To troubleshoot using the AWSSupport-TroubleshootRDP document

1. Log in to the Systems Manager Console.
2. Verify that you are in the same Region as the impaired instance.
3. Choose **Documents** from the left navigation pane.
4. On the **Owned by Amazon** tab, enter `AWSSupport-TroubleshootRDP` in the search field. When the `AWSSupport-TroubleshootRDP` document appears, select it.
5. Choose **Execute automation**.
6. For **Execution Mode**, choose **Simple execution**.
7. For **Input parameters**, **InstanceId**, enable **Show interactive instance picker**.
8. Choose your Amazon EC2 instance.
9. Review the examples, then choose **Execute**.
10. To monitor the execution progress, for **Execution status**, wait for the status to change from **Pending** to **Success**. Expand **Outputs** to view the results. To view the output of individual steps, in **Executed Steps**, choose an item from **Step ID.**

AWSSupport-TroubleshootRDP examples

The following examples show you how to accomplish common troubleshooting tasks using AWSSupport-TroubleshootRDP. You can use either the example AWS CLI start-automation-execution command or the provided link to the AWS Management Console.

Example: Check the current RDP status

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --
parameters "InstanceId=i-1234567890abcdef0, Action=Custom" --region region_code
```

AWS Systems Manager console:

```
https://eusc-de-east-1.console.amazonaws-eusc.eu/systems-manager/automation/execute/
AWSSupport-TroubleshootRDP?region=region#documentVersion=$LATEST
```

Example: Disable the Windows Firewall

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP"
 --parameters "InstanceId=i-1234567890abcdef0, Action=Custom, Firewall=Disable" --
region region_code
```

AWS Systems Manager console:

```
https://eusc-de-east-1.console.amazonaws-eusc.eu/systems-manager/automation/execute/
AWSSupport-TroubleshootRDP?region=region_code#documentVersion=$LATEST&Firewall=Disable
```

Example: Disable Network Level Authentication

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --
parameters "InstanceId=i-1234567890abcdef0, Action=Custom, NLASettingAction=Disable" --
region region_code
```

AWS Systems Manager console:

```
https://eusc-de-east-1.console.amazonaws-eusc.eu/systems-manager/automation/execute/
AWSSupport-TroubleshootRDP?region=region_code#documentVersion
```

Example: Set RDP Service Startup Type to Automatic and start the RDP service

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --
parameters "InstanceId=i-1234567890abcdef0, Action=Custom, RDPServiceStartupType=Auto,
 RDPServiceAction=Start" --region region_code
```

AWS Systems Manager console:

```
https://eusc-de-east-1.console.amazonaws-eusc.eu/systems-manager/automation/
execute/AWSSupport-TroubleshootRDP?region=region_code#documentVersion=
$LATEST&RDPServiceStartupType=Auto&RDPServiceAction=Start
```

Example: Restore the default RDP Port (3389)

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --
parameters "InstanceId=i-1234567890abcdef0, Action=Custom, RDPPortAction=Modify" --
region region_code
```

AWS Systems Manager console:

```
https://eusc-de-east-1.console.amazonaws-eusc.eu/systems-manager/automation/
execute/AWSSupport-TroubleshootRDP?region=region_code#documentVersion=
$LATEST&RDPPortAction=Modify
```

Example: Allow remote connections

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --
parameters "InstanceId=i-1234567890abcdef0, Action=Custom, RemoteConnections=Enable" --
region region_code
```

AWS Systems Manager console:

```
https://eusc-de-east-1.console.amazonaws-eusc.eu/systems-manager/automation/
execute/AWSSupport-TroubleshootRDP?region=region_code#documentVersion=
$LATEST&RemoteConnections=Enable
```

AWSSupport-ExecuteEC2Rescue

The AWSSupport-ExecuteEC2Rescue automation document uses EC2Rescue for Windows Server to automatically troubleshoot and restore EC2 instance connectivity and RDP issues. For more information, see Run the EC2Rescue tool on unreachable instances.

The AWSSupport-ExecuteEC2Rescue automation document requires a stop and restart of the instance. Systems Manager Automation stops the instance and creates an Amazon Machine Image (AMI). Data stored in instance store volumes is lost. The public IP address changes if you are not using an Elastic IP address. For more information, see Run the EC2Rescue tool on unreachable instances in the *AWS Systems Manager User Guide*.

To troubleshoot using the AWSSupport-ExecuteEC2Rescue document

1. Open the Systems Manager console.
2. Verify that you are in the same Region as the impaired Amazon EC2 instance.

3. In the navigation panel, choose **Documents**.
4. Search for and select the `AWSSupport-ExecuteEC2Rescue` document, and then choose **Execute automation**.
5. In **Execution Mode**, choose **Simple execution**.
6. In the **Input parameters** section, for **UnreachableInstanceId**, enter the Amazon EC2 instance ID of the unreachable instance.
7. (Optional) For **LogDestination**, enter the Amazon Simple Storage Service (Amazon S3) bucket name if you want to collect operating system logs for troubleshooting your Amazon EC2 instance. Logs are automatically uploaded to the specified bucket.
8. Choose **Execute**.
9. To monitor the execution progress, in **Execution status**, wait for the status to change from **Pending** to **Success**. Expand **Outputs** to view the results. To view the output of individual steps, in **Executed Steps**, choose the **Step ID**.

Enable Remote Desktop on an EC2 instance with remote registry

If your unreachable instance is not managed by AWS Systems Manager Session Manager, then you can use remote registry to enable Remote Desktop.

1. From the EC2 console, stop the unreachable instance.
2. Detach the root volume of the unreachable instance and attach it to a reachable instance in the same Availability Zone as a storage volume. If you don't have a reachable instance in the same Availability Zone, launch one. Note the device name of the root volume on the unreachable instance.
3. On the reachable instance, open Disk Management. You can do so by running the following command in the Command Prompt window.

   ```
   diskmgmt.msc
   ```

4. Open the context (right-click) menu for the newly attached volume that came from the unreachable instance, and then choose **Online**.
5. Open the Windows Registry Editor. You can do so by running the following command in the Command Prompt window.

   ```
   regedit
   ```

6. In Registry Editor, choose **HKEY_LOCAL_MACHINE**, then select **File**, **Load Hive**.
7. Select the drive of the attached volume, navigate to `\Windows\System32\config\`, select `SYSTEM`, and then choose **Open**.
8. For **Key Name**, enter a unique name for the hive and choose **OK**.
9. Back up the registry hive before making any changes to the registry.
   a. In the Registry Editor console tree, select the hive that you loaded: **HKEY_LOCAL_MACHINE***your-key-name*.
   b. Choose **File**, **Export**.
   c. In the Export Registry File dialog box, choose the location to which you want to save the backup copy, and then type a name for the backup file in the **File name** field.
   d. Choose **Save**.
10. In Registry Editor, navigate to `HKEY_LOCAL_MACHINE\`*your key name*`\ControlSet001\Control\Terminal Server`, and then, in the details pane, open **fDenyTSConnections**.
11. In the **Edit DWORD** value box, enter `0` in the **Value data** field.
12. Choose **OK**.

> **Note**
>
> If the value in the **Value data** field is `1`, then the instance will deny remote desktop connections. A value of `0` allows remote desktop connections.

13. In Registry Editor, choose **HKEY_LOCAL_MACHINE***your-key-name*, then select **File**, **Unload Hive**.
14. Close Registry Editor and Disk Management.
15. From the EC2 console, detach the volume from the reachable instance and then reattach it to the unreachable instance. When attaching the volume to the unreachable instance, enter the device name that you saved earlier in the **device** field.
16. Restart the unreachable instance.

I've lost my private key. How can I connect to my Windows instance?

When you connect to a newly-launched Windows instance, you decrypt the password for the Administrator account using the private key for the key pair that you specified when you launched the instance.

If you lose the Administrator password and you no longer have the private key, you must reset the password or create a new instance. For more information, see Reset the Windows administrator password for an Amazon EC2 Windows instance. For steps to reset the password using an Systems Manager document, see Reset passwords and SSH keys on EC2 instances in the *AWS Systems Manager User Guide*.

Troubleshoot Amazon EC2 Windows instance start issues

The following are troubleshooting tips to help you solve password and activation issues with Amazon EC2 Windows instances.

Issues

- "Password is not available"
- "Password not available yet"
- "Cannot retrieve Windows password"
- "Waiting for the metadata service"
- "Unable to activate Windows"
- "Windows is not genuine (0x80070005)"
- "No Terminal Server License Servers available to provide a license"
- "Some settings are managed by your organization"

"Password is not available"

To connect to a Windows instance using Remote Desktop, you must specify an account and password. The accounts and passwords provided are based on the AMI that you used to launch the instance. You can either retrieve the auto-generated password for the Administrator account, or use the account and password that were in use in the original instance from which the AMI was created.

You can generate a password for the Administrator account for instances launched using a custom Windows AMI. To generate the password, you will need to configure some settings in the operating system before the AMI is created. For more information, see Create an Amazon EBS-backed AMI.

If your Windows instance isn't configured to generate a random password, you'll receive the following message when you retrieve the auto-generated password using the console:

```
Password is not available.
The instance was launched from a custom AMI, or the default password has changed. A
password cannot be retrieved for this instance. If you have forgotten your password,
 you can
reset it using the Amazon EC2 configuration service. For more information, see
 Passwords for a
Windows Server instance.
```

Check the console output for the instance to see whether the AMI that you used to launch it was created with password generation disabled. If password generation is disabled, the console output contains the following:

```
Ec2SetPassword: Disabled
```

If password generation is disabled and you don't remember the password for the original instance, you can reset the password for this instance. For more information, see Reset the Windows administrator password for an Amazon EC2 Windows instance.

"Password not available yet"

To connect to a Windows instance using Remote Desktop, you must specify an account and password. The accounts and passwords provided are based on the AMI that you used to launch the instance. You can either retrieve the auto-generated password for the Administrator account, or use the account and password that were in use in the original instance from which the AMI was created.

Your password should be available within a few minutes. If the password isn't available, you'll receive the following message when you retrieve the auto-generated password using the console:

```
Password not available yet.
Please wait at least 4 minutes after launching an instance before trying to retrieve
 the
auto-generated password.
```

If it's been longer than four minutes and you still can't get the password, it's possible that the launch agent for your instance is not configured to generate a password. Verify by checking whether the console output is empty. For more information, see Unable to get console output.

Also verify that the AWS Identity and Access Management (IAM) account being used to access the Management Portal has the `ec2:GetPasswordData` action allowed. For more information about IAM permissions, see What is IAM?.

"Cannot retrieve Windows password"

To retrieve the auto-generated password for the Administrator account, you must use the private key for the key pair that you specified when you launched the instance. If you didn't specify a key pair when you launched the instance, you'll receive the following message.

```
Cannot retrieve Windows password
```

You can terminate this instance and launch a new instance using the same AMI, making sure to specify a key pair.

"Waiting for the metadata service"

A Windows instance must obtain information from its instance metadata before it can activate itself. By default, the `WaitForMetaDataAvailable` setting ensures that the EC2Config service waits for the instance metadata to be accessible before continuing with the boot process. For more information, see Use instance metadata to manage your EC2 instance.

If the instance is failing the instance reachability test, try the following to resolve this issue.

- Check the CIDR block for your VPC. A Windows instance cannot boot correctly if it's launched into a VPC that has an IP address range from `224.0.0.0` to `255.255.255.255` (Class D and Class E IP address ranges). These IP address ranges are reserved, and should not be assigned to host devices. We recommend that you create a VPC with a CIDR block from the private (non-publicly routable) IP address ranges as specified in RFC 1918.
- It's possible that the system has been configured with a static IP address. Try creating a network interface and attaching it to the instance.
- **To enable DHCP on a Windows instance that you can't connect to**

  1. Stop the affected instance and detach its root volume.
  2. Launch a temporary instance in the same Availability Zone as the affected instance.

> **Warning**
>
> If your temporary instance is based on the same AMI that the original instance is based on, you must complete additional steps or you won't be able to boot the original instance after you restore its root volume because of a disk signature collision. Alternatively, select a different AMI for the temporary instance. For example, if the original instance uses the AWS Windows AMI for Windows Server 2016, launch the temporary instance using the AWS Windows AMI for Windows Server 2019.

3. Attach the root volume from the affected instance to this temporary instance. Connect to the temporary instance, open the **Disk Management** utility, and bring the drive online.
4. From the temporary instance, open **Regedit** and select **HKEY_LOCAL_MACHINE**. From the **File** menu, choose **Load Hive**. Select the drive, open the file `Windows\System32\config\SYSTEM`, and specify a key name when prompted (you can use any name).
5. Select the key that you just loaded and navigate to `ControlSet001\Services\Tcpip\Parameters\Interfaces`. Each network interface is listed by a GUID. Select the correct network interface. If DHCP is disabled and a static IP address assigned, `EnableDHCP` is set to 0. To enable DHCP, set `EnableDHCP` to 1, and delete the following keys if they exist: `NameServer`, `SubnetMask`, `IPAddress`, and `DefaultGateway`. Select the key again, and from the **File** menu, choose **Unload Hive**.

   > **Note**
   >
   > If you have multiple network interfaces, you'll need to identify the correct interface to enable DHCP. To identify the correct network interface, review the following key values `NameServer`, `SubnetMask`, `IPAddress`, and `DefaultGateway`. These values display the static configuration of the previous instance.

6. (Optional) If DHCP is already enabled, it's possible that you don't have a route to the metadata service. Updating EC2Config can resolve this issue.

   a. Download and install the latest version of the EC2Config service. For more information about installing this service, see the section called “Install EC2Config”.

   b. Extract the files from the `.zip` file to the `Temp` directory on the drive you attached.

c. Open **Regedit** and select **HKEY_LOCAL_MACHINE**. From the **File** menu, choose **Load Hive**. Select the drive, open the file `Windows\System32\config\SOFTWARE`, and specify a key name when prompted (you can use any name).

d. Select the key that you just loaded and navigate to `Microsoft\Windows\CurrentVersion`. Select the `RunOnce` key. (If this key doesn't exist, right-click `CurrentVersion`, point to **New**, select **Key**, and name the key `RunOnce`.) Open the context (right-click) menu, point to **New**, and select **String Value**. Enter `Ec2Install` as the name and `C:\Temp\Ec2Install.exe -q` as the data.

e. Select the key again, and from the **File** menu, choose **Unload Hive**.

7. (Optional) If your temporary instance is based on the same AMI that the original instance is based on, you must complete the following steps or you won't be able to boot the original instance after you restore its root volume because of a disk signature collision.

> **⚠ Warning**
>
> The following procedure describes how to edit the Windows Registry using Registry Editor. If you are not familiar with the Windows Registry or how to safely make changes using Registry Editor, see Configure the Registry.

a. Open a command prompt, type **regedit.exe**, and press Enter.

b. In the **Registry Editor**, choose **HKEY_LOCAL_MACHINE** from the context menu (right-click), and then choose **Find**.

c. Type **Windows Boot Manager** and then choose **Find Next**.

d. Choose the key named `11000001`. This key is a sibling of the key you found in the previous step.

e. In the right pane, choose `Element` and then choose **Modify** from the context menu (right-click).

f. Locate the four-byte disk signature at offset 0x38 in the data. Reverse the bytes to create the disk signature, and write it down. For example, the disk signature represented by the following data is `E9EB3AA5`:

```
...
0030  00 00 00 00 01 00 00 00
0038  A5 3A EB E9 00 00 00 00
0040  00 00 00 00 00 00 00 00
```

```
...
```

g. In a Command Prompt window, run the following command to start Microsoft DiskPart.

```
diskpart
```

h. Run the following DiskPart command to select the volume. (You can verify that the disk number is 1 using the **Disk Management** utility.)

```
DISKPART> select disk 1

Disk 1 is now the selected disk.
```

i. Run the following DiskPart command to get the disk signature.

```
DISKPART>  uniqueid disk

Disk ID: 0C764FA8
```

j. If the disk signature shown in the previous step doesn't match the disk signature from BCD that you wrote down earlier, use the following DiskPart command to change the disk signature so that it matches:

```
DISKPART> uniqueid disk id=E9EB3AA5
```

8. Using the **Disk Management** utility, bring the drive offline.

> **Note**
>
> The drive is automatically offline if the temporary instance is running the same operating system as the affected instance, so you won't need to bring it offline manually.

9. Detach the volume from the temporary instance. You can terminate the temporary instance if you have no further use for it.
10. Restore the root volume of the affected instance by attaching the volume as `/dev/sda1`.
11. Start the affected instance.

If you are connected to the instance, open an Internet browser from the instance and enter the following URL for the metadata server:

```
http://169.254.169.254/latest/meta-data/
```

If you can't contact the metadata server, try the following to resolve the issue:

- Download and install the latest version of the EC2Config service. For more information about installing this service, see the section called “Install EC2Config”.
- Check whether the Windows instance is running Red Hat PV drivers. If so, update to Citrix PV drivers. For more information, see the section called “Upgrade PV drivers”.
- Verify that the firewall, IPSec, and proxy settings do not block outgoing traffic to the metadata service (`169.254.169.254`) or the AWS KMS servers (the addresses are specified in `TargetKMSServer` elements in `C:\Program Files\Amazon\Ec2ConfigService\Settings\ActivationSettings.xml`).
- Verify that you have a route to the metadata service (`169.254.169.254`) using the following command.

  ```
  route print
  ```

- Check for network issues that might affect the Availability Zone for your instance. Go to http://status.www.aws.eu/.

"Unable to activate Windows"

Windows instances use Windows AWS KMS activation. You can receive this message: `A problem occurred when Windows tried to activate. Error Code 0xC004F074`, if your instance can't reach the AWS KMS server. Windows must be activated every 180 days. EC2Config attempts to contact the AWS KMS server before the activation period expires to ensure that Windows remains activated.

If you encounter a Windows activation issue, use the following procedure to resolve the issue.

For EC2Config (Windows Server 2012 R2 AMIs and earlier)

1. Download and install the latest version of the EC2Config service. For more information about installing this service, see the section called “Install EC2Config”.

2. Log onto the instance and open the following file: `C:\Program Files\Amazon\Ec2ConfigService\Settings\config.xml`.
3. Locate the **Ec2WindowsActivate** plugin in the `config.xml` file. Change the state to **Enabled** and save your changes.
4. In the Windows Services snap-in, restart the EC2Config service or reboot the instance.

If this does not resolve the activation issue, follow these additional steps.

1. Set the AWS KMS target: **C:\> slmgr.vbs /skms 169.254.169.250:1688**
2. Activate Windows: **C:\> slmgr.vbs /ato**

For EC2Launch (Windows Server 2016 AMIs and later)

1. From a PowerShell prompt with administrative rights, import the EC2Launch module:

```
PS C:\> Import-Module "C:\ProgramData\Amazon\EC2-Windows\Launch\Module
\Ec2Launch.psd1"
```

2. Call the Add-Routes function to see the list of new routes:

```
PS C:\> Add-Routes
```

3. Call the Set-ActivationSettings function:

```
PS C:\> Set-Activationsettings
```

4. Then, run the following script to activate Windows:

```
PS C:\> cscript "${env:SYSTEMROOT}\system32\slmgr.vbs" /ato
```

For both EC2Config and EC2Launch, if you are still receiving an activation error, verify the following information.

- Verify that you have routes to the AWS KMS servers. Open `C:\Program Files\Amazon\Ec2ConfigService\Settings\ActivationSettings.xml` and locate the `TargetKMSServer` elements. Run the following command and check whether the addresses for these AWS KMS servers are listed.

```
route print
```

- Verify that the AWS KMS client key is set. Run the following command and check the output.

  ```
  C:\Windows\System32\slmgr.vbs /dlv
  ```

  If the output contains Error: product key not found, the AWS KMS client key isn't set. If the AWS KMS client key isn't set, look up the client key as described in this Microsoft article: AWS KMS client activation and product keys, and then run the following command to set the AWS KMS client key.

  ```
  C:\Windows\System32\slmgr.vbs /ipk client_key
  ```

- Verify that the system has the correct time and time zone. If you are using a time zone other than UTC, add the following registry key and set it to 1 to ensure that the time is correct: `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\TimeZoneInformation\RealTimeIsUniversal`.
- If Windows Firewall is enabled, temporarily disable it using the following command.

  ```
  netsh advfirewall set allprofiles state off
  ```

"Windows is not genuine (0x80070005)"

Windows instances use Windows AWS KMS activation. If an instance is unable to complete the activation process, it reports that the copy of Windows is not genuine.

Try the suggestions for "Unable to activate Windows".

"No Terminal Server License Servers available to provide a license"

By default, Windows Server is licensed for two simultaneous users through Remote Desktop. If you need to provide more than two users with simultaneous access to your Windows instance through Remote Desktop, you can purchase a Remote Desktop Services client access license (CAL) and install the Remote Desktop Session Host and Remote Desktop Licensing Server roles.

Check for the following issues:

- You've exceeded the maximum number of concurrent RDP sessions.

- You've installed the Windows Remote Desktop Services role.
- Licensing has expired. If the licensing has expired, you can't connect to your Windows instance as a user. You can try the following:
  - Connect to the instance from the command line using an `/admin` parameter, for example:

    ```
    mstsc /v:instance /admin
    ```

    For more information, see the following Microsoft article: Access Remote Desktop Via Command Line.
  - Stop the instance, detach its Amazon EBS volumes, and attach them to another instance in the same Availability Zone to recover your data.

"Some settings are managed by your organization"

Instances launched from the latest Windows Server AMIs might show a Windows Update dialog message stating "Some settings are managed by your organization." This message appears as a result of changes in Windows Server and does not impact the behavior of Windows Update or your ability to manage update settings.

To remove the warning

1. Open `gpedit.msc` and navigate to **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Windows updates**. Edit **Configure Automatic Update**, and set it to **enabled**.
2. In a command prompt, update group policy using **gpupdate /force**.
3. Close and reopen the Windows Update Settings. You will see the above message about your settings being managed by your organization, followed by "We'll automatically download updates, except on metered connections (where charges may apply). In that case, we'll automatically download those updates required to keep Windows running smoothly."
4. Return to `gpedit.msc` and set the group policy back to **not configured**. Run **gpupdate /force** again.
5. Close the command prompt and wait a few minutes.
6. Reopen the Windows Update Settings. You should not see the message "Some settings are managed by your organization."

Troubleshoot issues with Amazon EC2 Windows instances

The following are troubleshooting tips to help you solve the issues with Amazon EC2 Windows instances.

Issues

- Unable to connect AWS Systems Manager Sessions Manager to a Windows Server 2025 instance
- EBS volumes don't initialize on Windows Server 2016 and 2019
- Boot an EC2 Windows instance into Directory Services Restore Mode (DSRM)
- Instance loses network connectivity or scheduled tasks don't run when expected
- Unable to get console output
- Windows Server 2012 R2 not available on the network
- Disk signature collision

Unable to connect AWS Systems Manager Sessions Manager to a Windows Server 2025 instance

You may encounter an issue connecting AWS Systems Manager Sessions Manager to a Windows Server 2025 instance. To address this issue, log onto the instance, then navigate to `Settings > Apps > Optional Features`, and add `WMIC`. Restart the SSM Agent service or reboot the instance, and Sessions Manager should connect.

You can also use the following PowerShell command to perform the same action:

```
Start-Process -FilePath "$env:SystemRoot\system32\Dism.exe" -ArgumentList @('/
Online', '/Add-Capability', '/CapabilityName:WMIC~~~~') -Wait; Restart-Service -Name
 AmazonSSMAgent
```

EBS volumes don't initialize on Windows Server 2016 and 2019

Instances created from Amazon Machine Images (AMIs) for Windows Server 2016 and 2019 use the EC2Launch v1 agent for a variety of startup tasks, including initializing EBS volumes. By default, EC2Launch v1 doesn't initialize secondary volumes. However, you can configure EC2Launch v1 to initialize these disks automatically, as follows.

Map drive letters to volumes

1. Connect to the instance to configure and open the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config\DriveLetterMappingConfig.json` file in a text editor.
2. Specify the volume settings as follows:

```
{
"driveLetterMapping": [
 {
   "volumeName": "sample volume",
   "driveLetter": "H"
 }]
}
```

3. Save your changes and close the file.
4. Open Windows PowerShell and use the following command to run the EC2Launch v1 script that initializes the disks:

```
PS C:\>  C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeDisks.ps1
```

To initialize the disks each time the instance boots, add the `-Schedule` flag as follows:

```
PS C:\>  C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeDisks.ps1 -
Schedule
```

The EC2Launch v1 agent can run instance initialization scripts such as `initializeDisks.ps1` in parallel with the `InitializeInstance.ps1` script. If the `InitializeInstance.ps1` script reboots the instance, it might interrupt other scheduled tasks that run at instance startup. To avoid any potential conflicts, we recommend that you add logic to your `initializeDisks.ps1` script to ensure that instance initialization has finished first.

> **Note**
>
> If the EC2Launch script does not initialize the volumes, ensure that the volumes are online. If the volumes are offline, run the following command to bring all disks online.

```
PS C:\> Get-Disk | Where-Object IsOffline -Eq $True | Set-Disk -IsOffline
 $False
```

Boot an EC2 Windows instance into Directory Services Restore Mode (DSRM)

If an instance running Microsoft Active Directory experiences a system failure or other critical issues you can troubleshoot the instance by booting into a special version of Safe Mode called *Directory Services Restore Mode* (DSRM). In DSRM you can repair or recover Active Directory.

Driver support for DSRM

How you enable DSRM and boot into the instance depends on the drivers the instance is running. In the EC2 console you can view driver version details for an instance from the System Log. The following table shows which drivers are supported for DSRM.

Driver Versions	DSRM Supported?	Next Steps
Citrix PV 5.9	No	Restore the instance from a backup. You cannot enable DSRM.
AWS PV 7.2.0	No	Though DSRM is not supported for this driver, you can still detach the root volume from the instance, take a snapshot of the volume or create an AMI from it, and attach it to another instance in the same Availability Zone as a secondary volume. You can then enable DSRM (as described in this section).
AWS PV 7.2.2 and later	Yes	Detach the root volume, attach it to another instance, and enable DSRM (as described in this section).
Enhanced Networking	Yes	Detach the root volume, attach it to another instance, and enable DSRM (as described in this section).

For information about how to enable enhanced networking, see the section called "Elastic Network Adapter (ENA)". For information about upgrading AWS PV drivers, see Upgrade PV drivers on Windows instances.

Configure an instance to boot into DSRM

EC2 Windows instances do not have network connectivity before the operating system is running. For this reason, you cannot press the F8 button on your keyboard to select a boot option. You must use one of the following procedures to boot an EC2 Windows Server instance into DSRM.

If you suspect that Active Directory has been corrupted and the instance is still running, you can configure the instance to boot into DSRM using either the System Configuration dialog box or the command prompt.

To boot an online instance into DSRM using the System Configuration dialog box

1. In the **Run** dialog box, type `msconfig` and press Enter.
2. Choose the **Boot** tab.
3. Under **Boot options** choose **Safe boot**.
4. Choose **Active Directory repair** and then choose **OK**. The system prompts you to reboot the server.

To boot an online instance into DSRM using the command line

From a Command Prompt window, run the following command:

```
bcdedit /set safeboot dsrepair
```

If an instance is offline and unreachable, you must detach the root volume and attach it to another instance to enable DSRM mode.

To boot an offline instance into DSRM

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Locate and select the affected instance. Choose **Instance state**, **Stop instance**.
4. Choose **Launch instances** and create a temporary instance in the same Availability Zone as the affected instance. Choose an instance type that uses a different version of Windows.

For example, if your instance is Windows Server 2016, then choose a Windows Server 2019 instance.

> **Important**
>
> If you do not create the instance in the same Availability Zone as the affected instance you will not be able to attach the root volume of the affected instance to the new instance.

5. In the navigation pane, choose **Volumes**.
6. Locate the root volume of the affected instance. Detach the volume and attach it to the temporary instance you created earlier. Attach it with the default device name (xvdf).
7. Use Remote Desktop to connect to the temporary instance, and then use the Disk Management utility to make the volume available for use.
8. Open a command prompt and run the following command. Replace *D* with the actual drive letter of the secondary volume you just attached:

```
bcdedit /store D:\Boot\BCD /set {default} safeboot dsrepair
```

9. In the Disk Management Utility, choose the drive you attached earlier, open the context (right-click) menu, and choose **Offline**.
10. In the EC2 console, detach the affected volume from the temporary instance and reattach it to your original instance with the device name `/dev/sda1`. You must specify this device name to designate the volume as a root volume.
11. Start the instance.
12. After the instance passes the health checks in the EC2 console, connect to the instance using Remote Desktop and verify that it boots into DSRM mode.
13. (Optional) Delete or stop the temporary instance you created in this procedure.

Instance loses network connectivity or scheduled tasks don't run when expected

If you restart your instance and it loses network connectivity, it's possible that the instance has the wrong time.

By default, Windows instances use Coordinated Universal Time (UTC). If you set the time for your instance to a different time zone and then restart it, the time becomes offset and the instance temporarily loses its IP address. The instance regains network connectivity eventually, but this can take several hours. The amount of time that it takes for the instance to regain network connectivity depends on the difference between UTC and the other time zone.

This same time issue can also result in scheduled tasks not running when you expect them to. In this case, the scheduled tasks do not run when expected because the instance has the incorrect time.

To use a time zone other than UTC persistently, you must set the **RealTimeIsUniversal** registry key. Without this key, an instance uses UTC after you restart it.

To resolve time issues that cause a loss of network connectivity

1. Ensure that you are running the recommended PV drivers. For more information, see the section called “Upgrade PV drivers”.
2. Verify that the following registry key exists and is set to 1: **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\TimeZoneInformation\RealTimeIsUniversal**

Unable to get console output

For Windows instances, the instance console displays the output from tasks performed during the Windows boot process. If Windows boots successfully, the last message logged is `Windows is Ready to use`. You can also display event log messages in the console, but this feature might not be enabled by default depending on your version of Windows. For more information, see the section called “Windows launch agents”.

To get the console output for your instance using the Amazon EC2 console, select the instance, and then choose **Actions**, **Monitor and troubleshoot**, **Get system log**. To get the console output using the command line, use one of the following commands: get-console-output (AWS CLI) or Get-EC2ConsoleOutput (AWS Tools for Windows PowerShell).

For instances running Windows Server 2012 R2 and earlier, if the console output is empty, it could indicate an issue with the EC2Config service, such as a misconfigured configuration file, or that Windows failed to boot properly. To fix the issue, download and install the latest version of EC2Config. For more information, see the section called “Install EC2Config”.

Windows Server 2012 R2 not available on the network

For information about troubleshooting a Windows Server 2012 R2 instance that is not available on the network, see Windows Server 2012 R2 loses network and storage connectivity after an instance reboot.

Disk signature collision

You can check for and resolve disk signature collisions using EC2Rescue for Windows Server. Or, you can manually resolve disk signature issues by performing the following steps.

> **Warning**
>
> The following procedure describes how to edit the Windows Registry using Registry Editor. If you are not familiar with the Windows Registry or how to safely make changes using Registry Editor, see Configure the Registry.

1. Open a command prompt, type **regedit.exe**, and press Enter.
2. In the **Registry Editor**, choose **HKEY_LOCAL_MACHINE** from the context menu (right-click), and then choose **Find**.
3. Type **Windows Boot Manager** and then choose **Find Next**.
4. Choose the key named `11000001`. This key is a sibling of the key you found in the previous step.
5. In the right pane, choose `Element` and then choose **Modify** from the context menu (right-click).
6. Locate the four-byte disk signature at offset 0x38 in the data. This is the Boot Configuration Database signature (BCD). Reverse the bytes to create the disk signature, and write it down. For example, the disk signature represented by the following data is E9EB3AA5:

```
...
0030  00 00 00 00 01 00 00 00
0038  A5 3A EB E9 00 00 00 00
0040  00 00 00 00 00 00 00 00
...
```

7. In a Command Prompt window, run the following command to start Microsoft DiskPart.

```
diskpart
```

8. Run the `select disk` DiskPart command and specify the disk number for the volume with the disk signature collision.

> **Tip**
>
> To check the disk number for the volume with the disk signature collision, use the **Disk Management** utility. Open a command prompt, type `compmgmt.msc` and press **Enter**. In the left-hand navigation panel, open **Disk Management**. In the **Disk Management** utility, check the disk number for the offline volume with the disk signature collision.

```
DISKPART> select disk 1
Disk 1 is now the selected disk.
```

9. Run the following DiskPart command to get the disk signature.

```
DISKPART>  uniqueid disk
Disk ID: 0C764FA8
```

10. If the disk signature shown in the previous step doesn't match the disk signature that you wrote down earlier, use the following DiskPart command to change the disk signature so that it matches:

```
DISKPART> uniqueid disk id=E9EB3AA5
```

Kernel debugging for Windows instances over the network

The KDNET Extensibility Module for Elastic Network Adapter (ENA) is a hardware driver support layer that enables Windows kernel debugging over the network through ENA on Amazon Elastic Compute Cloud instances. You can use the extensibility module with the Windows Debugger (WinDbg) to perform kernel-level debugging on EC2 instances running Windows.

Kernel debugging helps you diagnose and troubleshoot low-level operating system issues such as blue screen errors (BSODs), driver failures, and boot problems on your EC2 Windows instances.

Contents

- Prerequisites
- Step 1: Install Windows Debugging Tools on the debug host
- Step 2: Set up the debug target
- Step 3: Start the debugging session on the debug host
- Step 4: Reboot the debug target
- Clean up debug settings after debugging
- Limitations
- Additional notes

Prerequisites

Before you begin, make sure you have the following:

Two EC2 Windows instances, in the same subnet:

- A **debug host** instance — runs the Windows Debugger (WinDbg).
- A **debug target** instance — the instance you want to debug.

For more information about launching instances, see *Get started tutorial*.

Security groups for the host and target instances must allow inbound and outbound UDP traffic on the port used for KDNET debugging (recommended range: 50000–50039). The simplest way to set this up is to create a security group with an inbound rule that allows UDP traffic from itself as the source, and then attach that security group to both instances. For more information, see Security group rules in the *Amazon VPC User Guide*.

The debug target instance must run one of these Windows versions (or later):

- Windows Server 2025 with build number 26100.7462 (December 2025 patch)
- Windows 11 24H2 with build number 26100.7309
- Windows 11 25H2 with build number 26200.7309

Note

The KDNET extensibility module for ENA is distributed as part of Windows and can only be updated through Windows monthly cumulative updates. We recommend keeping the latest Windows KB installed on the debug target to ensure you have the most recent version of it. To verify that the module is present on the debug target, run the following command in an elevated PowerShell session:

```
Test-Path C:\Windows\system32\kd_02_1d0f.dll
```

If the command returns `True`, the module is available.

Step 1: Install Windows Debugging Tools on the debug host

Install the Windows Debugging Tools on the debug host instance by running the following command in a PowerShell session:

```
winget install microsoft.windbg
```

For detailed installation instructions, see Install the Windows Debugger in the Microsoft documentation.

After installation, verify that the debugger is working by running the following command in a PowerShell session:

```
windbgx
```

The WinDbg window should open. If it does, the installation was successful and you can close the window.

Step 2: Set up the debug target

Note

When kernel debugging is active, the ENA device used for the debugging session is dedicated to debugger traffic only. If you need to maintain internet access on the debug target instance during debugging, attach a second ENA to the instance before you begin.

On the debug target, open an elevated PowerShell session and configure kernel debugging using the following steps.

Run the following command to list the bus, device, and function number of the ENA adapter attached to the instance:

```
Get-NetAdapter -Physical |
    Where-Object -Property PnPDeviceID -Match -Value '^PCI\\VEN_1D0F&DEV_EC2[01]&' |
    Get-NetAdapterHardwareInfo |
    Select-Object InterfaceDescription, BusNumber, DeviceNumber, FunctionNumber |
    Format-List
```

If multiple ENA adapters are attached to the instance

If multiple ENA adapters are attached to the instance, use the following command to map each physical adapter to its private IP address. You can cross-reference these details in the AWS Management Console under **EC2** → **Instances** → **[Instance ID]** → **Networking** → **Network interfaces**. This helps you correlate specific Network Interface IDs, private IPs, and security groups with the OS-level adapter for targeted debugging.

```
Get-NetAdapter -Physical |
    Where-Object PnPDeviceID -Match '^PCI\\VEN_1D0F&DEV_EC2[01]&' |
    ForEach-Object {
        $adapter = $_
        $hwInfo = $adapter | Get-NetAdapterHardwareInfo
        $ipInfo = Get-NetIPAddress -InterfaceIndex $adapter.InterfaceIndex -
AddressFamily IPv4
        [PSCustomObject]@{
            InterfaceDescription = $adapter.InterfaceDescription
            IPAddress            = $ipInfo.IPAddress
            BusNumber            = $hwInfo.BusNumber
            DeviceNumber         = $hwInfo.DeviceNumber
            FunctionNumber       = $hwInfo.FunctionNumber
        }
    } | Format-List
```

Note the `BusNumber`, `DeviceNumber`, and `FunctionNumber` values of the ENA adapter to be used for debugging from the output.

Run the following commands to configure kernel debugging. Replace the placeholder values with your specific configuration:

```
bcdedit /debug on
bcdedit /set loadoptions FORCEHVTONOTSHAREDEBUGDEVICE
bcdedit /dbgsettings net hostip:host-private-ip port:port-number key:encryption-key
 busparams:b.d.f
```

Note

Check for existing `loadoptions` by running the following command. If a value is returned, copy that string and append `;FORCEHVTONOTSHAREDEBUGDEVICE` to it.

```
(bcdedit /enum) -match "loadoptions"
```

Where:

- *`host-private-ip`* — The private IPv4 address of the debug host instance. If your instances are launched in an IPv6-only subnet, see Setting up KDNET with IPv6 in the Microsoft documentation to learn more about using IPv6 with KDNET.
- *`port-number`* — The port to use for the debugging session. The recommended range is 50000–50039 (for example, `50000`).
- *`encryption-key`* — A 256-bit key used to encrypt the debugging connection, specified as four 64-bit values separated by periods. Each 64-bit value can be up to 13 characters long using only lowercase letters a–z and digits 0–9. Special characters are not allowed. Example encryption key: `1kdnet2keys3.4kdnet5keys6.7kdnet8keys9.10kdnet11ke`.
- *`b.d.f`* — The bus, device, and function numbers for the ENA device, formatted as `bus.device.function` (for example, `0.3.0`), used for debugging.

Tip

To debug the Windows boot process, also run the following command:

```
bcdedit /bootdebug on
```

Step 3: Start the debugging session on the debug host

To allow debugging traffic on the host, you can create a firewall rule for either the WinDbg application or a specific UDP port.

Option 1: Allow the WinDbg application

Run the following commands to authorize the WinDbg executable:

```
$WinDbgxPath = "$env:LocalAppData\Microsoft\WindowsApps\WinDbgX.exe"
New-NetFirewallRule -DisplayName "Allow Inbound KDNET Connection" -Action Allow -
Program $WinDbgxPath
```

Option 2: Allow a specific UDP port

Alternatively, you can allow inbound UDP traffic to the port configured for kernel debugging. Replace *port-number* with your chosen KDNET port:

```
$DebugPort = port-number
New-NetFirewallRule -DisplayName "Allow Inbound KDNET Connection" -Direction Inbound -
LocalPort $DebugPort -Protocol UDP -Action Allow
```

> **Note**
>
> Firewall configurations may be restricted by Domain Group Policy (GPO) or require elevated Administrator permissions. If the command fails, contact your network administrator.

Start WinDbg with the port and key that match the debug target configuration. You can specify additional kernel debugging options documented in the Microsoft WinDbg command line reference to suit your use case.

```
windbgx -k net:port=port-number,key=encryption-key
```

WinDbg opens and waits for the debug target to connect.

Step 4: Reboot the debug target

On the debug target, restart the instance to initiate the debugging connection:

```
shutdown -r -t 0
```

After the debug target restarts, WinDbg on the debug host connects to the target automatically. You can now use WinDbg to inspect the kernel state, set breakpoints, and diagnose issues.

Clean up debug settings after debugging

On the debug target

After you finish debugging, remove the kernel debugging configuration from the debug target to restore normal boot behavior. On the debug target, open an elevated PowerShell session and run the following commands:

```
bcdedit /debug off
bcdedit /dbgsettings LOCAL
bcdedit /deletevalue loadoptions
```

If you have existing `loadoptions` other than `FORCEHVTONOTSHAREDEBUGDEVICE`, you should restore the setting by running `bcdedit /set loadoptions` with the original `loadoptions`.

If you enabled boot debugging, also run:

```
bcdedit /bootdebug off
```

Restart the instance for the changes to take effect.

On the debug host

Remove the firewall rule by running:

```
Remove-NetFirewallRule -DisplayName "Allow Inbound KDNET Connection"
```

Limitations

The KDNET extensibility module for ENA does not currently support:

- 8th generation non-metal x86_64 instance types (for example, `m8a.xlarge`)
- 7th generation 48xlarge non-metal x86_64 instance types (for example, `m7a.48xlarge`)
- u7i instance types

The module does not currently support instances with Secure Boot enabled. You can verify the status by running `Confirm-SecureBootUEFI` in an elevated PowerShell session. If the output is `True`, Secure Boot is active. Note that all Amazon-provided images with a 'TPM' prefix have Secure Boot enabled by default.

Additional notes

If you encounter issues connecting the debugger to the target instance, verify the following:

- All prerequisites listed in this guide are met, including the required Windows Server build version and the presence of the extensibility module.
- The security groups attached to both instances are configured correctly to allow traffic between them on the configured debugging port.
- Windows Firewall rules on the host instances do not block network traffic between the two instances on the configured port.

For additional guidance, see Set up KDNET network kernel debugging manually in the Microsoft documentation.

Troubleshoot your Windows instance using SAC

The Special Administration Console (SAC) capability of Windows provides a way to troubleshoot a Windows instance through the instance serial port. By connecting using the EC2 Serial Console, you can troubleshoot boot, network configuration, and other issues through SAC. You can interrupt the boot process or boot Windows in safe mode. With SAC, you can enter commands to an instance as if your keyboard and monitor are directly attached to the instance's serial port. The serial console does not require your instance to have any networking capabilities.

For the equivalent Linux troubleshooting tools (GRUB and SysRq), see Troubleshoot your Amazon EC2 instance using the EC2 Serial Console.

Topics

- Prerequisites
- Enable SAC and the boot menu
- Use SAC
- Built-in SAC commands
- Use the boot menu

- Known behaviors
- Disable SAC and the boot menu
- See also

Prerequisites

Using SAC requires access to the EC2 Serial Console. Before you begin, complete the steps in Prerequisites for the EC2 Serial Console and Configure access to the EC2 Serial Console. SAC must also be enabled on the instance. To enable SAC, see Enable SAC and the boot menu.

SAC requires at least the EC2Launch v2.5.0 agent and EC2WinUtil driver v3.2.0. EC2Launch v2 relies on the serial port to perform several initialization tasks during boot, such as emitting the instance password and RDP thumbprint. Wait until the instance fully initializes before you connect to the serial console. If you connect before EC2Launch v2 emits its output, or if the minimum required versions are not installed, you might not be able to retrieve the instance password or other console output.

For more information about EC2Launch v2, see Use the EC2Launch v2 agent to perform tasks during EC2 Windows instance launch.

Enable SAC and the boot menu

Before you can use SAC to troubleshoot an instance, you must enable SAC on the instance. You can optionally enable the boot menu so that you can interrupt the boot process.

> **Note**
>
> Starting with version 2026.09.09, SAC is enabled by default on the following AWS AMIs:
>
> - `EC2LaunchV2-Windows_Server-2019-English-Core-Base-*`
> - `EC2LaunchV2-Windows_Server-2019-English-Full-Base-*`
>
> If you launch these AMIs on bare metal instances, you must manually re-enable SAC using the following steps.

Use one of the following methods to enable SAC and the boot menu on an instance.

PowerShell

To enable SAC and the boot menu on a Windows instance

1. Connect to your instance and perform the following steps from an elevated PowerShell command line.
2. Enable SAC.

```
bcdedit /ems '{current}' on
bcdedit /emssettings EMSPORT:1 EMSBAUDRATE:115200
```

   On bare metal instances, use the following instead. This directs Windows to use the EMS serial port defined by the instance firmware.

```
bcdedit /ems '{current}' on
bcdedit /emssettings BIOS
```

3. (Optional) Enable the boot menu.

```
bcdedit /set '{bootmgr}' displaybootmenu yes
bcdedit /set '{bootmgr}' timeout 15
bcdedit /set '{bootmgr}' bootems yes
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Command prompt

To enable SAC and the boot menu on a Windows instance

1. Connect to your instance and perform the following steps from the command prompt.
2. Enable SAC.

```
bcdedit /ems {current} on
bcdedit /emssettings EMSPORT:1 EMSBAUDRATE:115200
```

   On bare metal instances, use the following instead. This directs Windows to use the EMS serial port defined by the instance firmware.

```
bcdedit /ems {current} on
bcdedit /emssettings BIOS
```

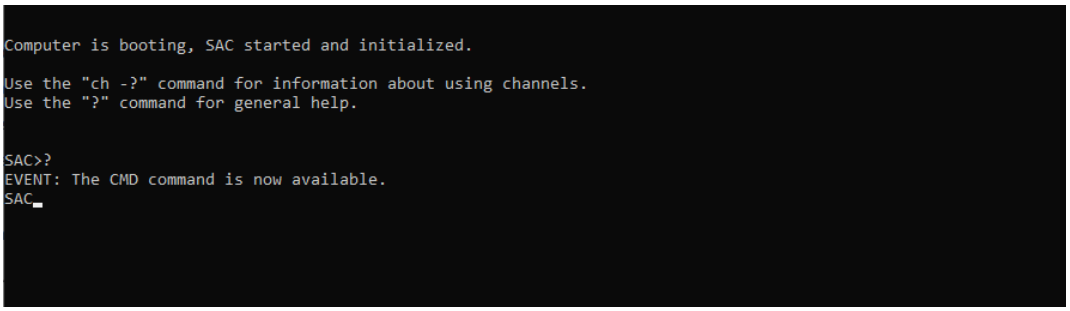
3. (Optional) Enable the boot menu.

```
bcdedit /set {bootmgr} displaybootmenu yes
bcdedit /set {bootmgr} timeout 15
bcdedit /set {bootmgr} bootems yes
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Use SAC



You can use SAC to open a shell channel for instance troubleshooting. Use one of the following methods to open a command prompt or PowerShell channel from the SAC> prompt.

PowerShell

To use PowerShell from SAC

1. Connect to the serial console.

   If SAC is enabled on the instance, the serial console displays the SAC> prompt. You might see a blank screen instead of the SAC> prompt. Press **Enter** to display the SAC> prompt.

2. To list available commands, enter ?, and then press **Enter**.

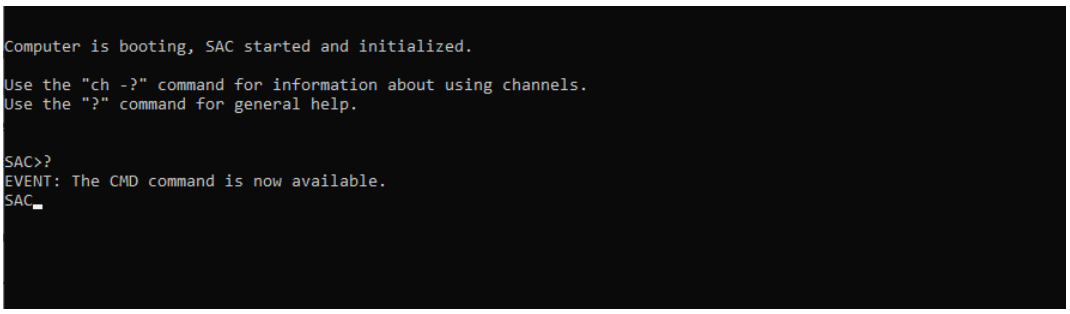
```
SAC>?
ch                  Channel management commands.  Use ch -? for more help.
cmd                 Create a Command Prompt channel.
d                   Dump the current kernel log.
f                   Toggle detailed or abbreviated tlist info.
? or help           Display this list.
i                   List all IP network numbers and their IP addresses.
i <#> <ip> <subnet> <gateway> Set IPv4 addr., subnet and gateway.
id                  Display the computer identification information.
k <pid>             Kill the given process.
l <pid>             Lower the priority of a process to the lowest possible.
lock                Lock access to Command Prompt channels.
m <pid> <MB-allow>  Limit the memory usage of a process to <MB-allow>.
p                   Toggle paging the display.
r <pid>             Raise the priority of a process by one.
s                   Display the current time and date (24 hour clock used).
s mm/dd/yyyy hh:mm  Set the current time and date (24 hour clock used).
t                   Tlist.
restart             Restart the system immediately.
shutdown            Shutdown the system immediately.
crashdump           Crash the system. You must have crash dump enabled.
```

3. To create a command prompt channel (such as `cmd0001` or `cmd0002`), enter `cmd`, and then press **Enter**.
4. To view the command prompt channel, press **ESC**, and then press **TAB**.
5. To switch channels, press **ESC+TAB+channel number** together. For example, to switch to the `cmd0002` channel (if it has been created), press **ESC+TAB+2**.
6. Enter the credentials required by the command prompt channel.
7. Start PowerShell from the command prompt channel.

   ```
   powershell
   ```

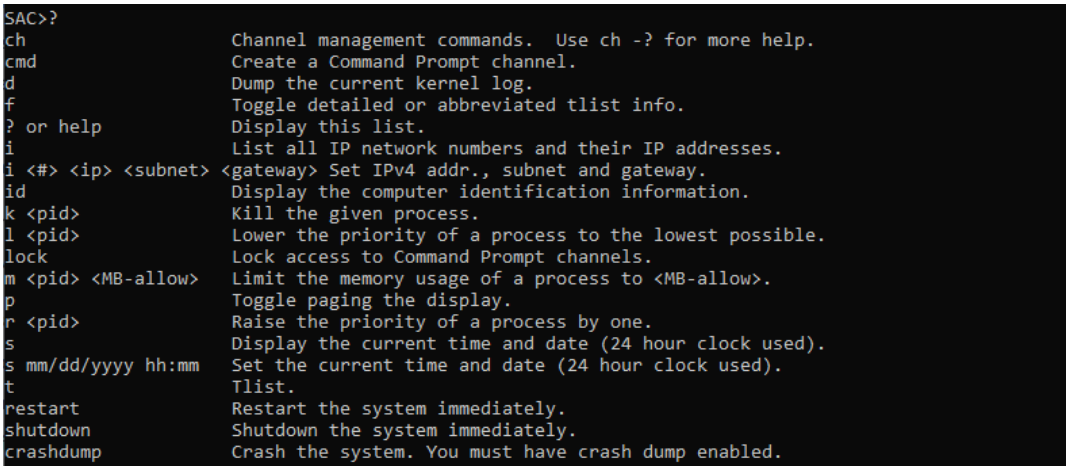
   To prevent progress output from interfering with the serial console, set the progress preference to silent mode.

   ```
   $ProgressPreference = "SilentlyContinue"
   ```



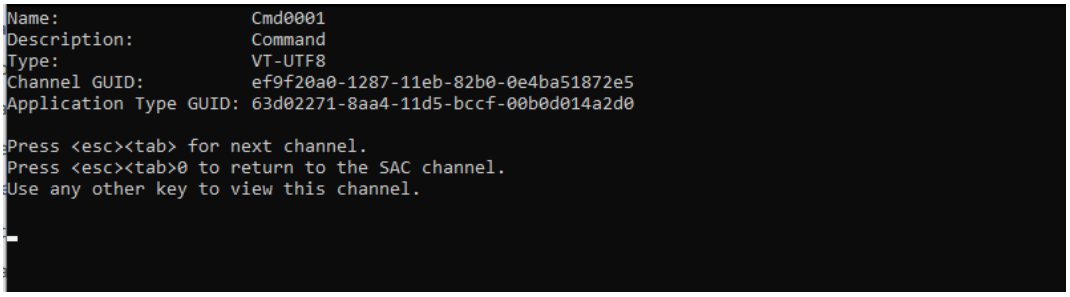
```
PS C:\Windows\system32> $ProgressPreference="SilentlyContinue"
PS C:\Windows\system32> $computerInfo = Get-ComputerInfo
PS C:\Windows\system32> $computerInfo.Csprocessors[0].Name
Intel(R) Xeon(R) Platinum 8124M CPU @ 3.00GHz
PS C:\Windows\system32> $computerInfo.Csprocessors[0].Description
Intel64 Family 6 Model 85 Stepping 4
PS C:\Windows\system32>
```

Command prompt



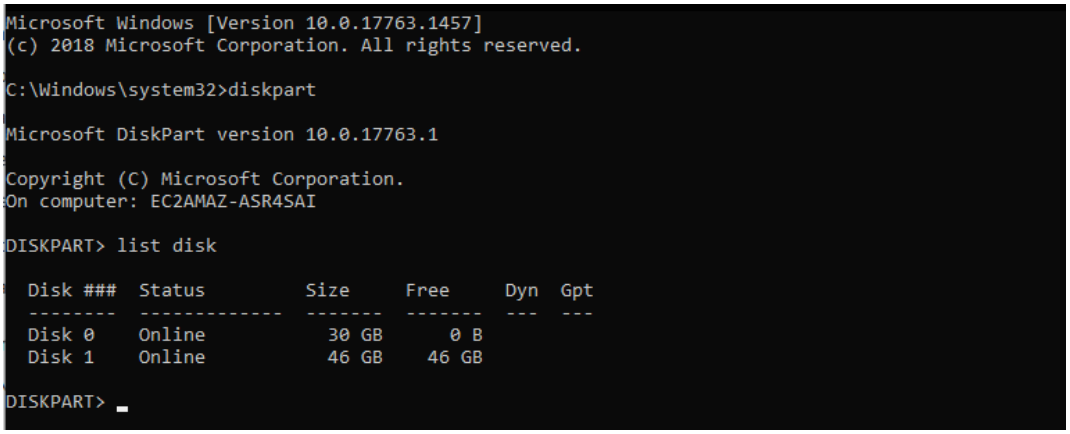
To use the command prompt from SAC

1. Connect to the serial console.



If SAC is enabled on the instance, the serial console displays the SAC> prompt. You might see a blank screen instead of the SAC> prompt. Press **Enter** to display the SAC> prompt.

2. To list available commands, enter ?, and then press **Enter**.



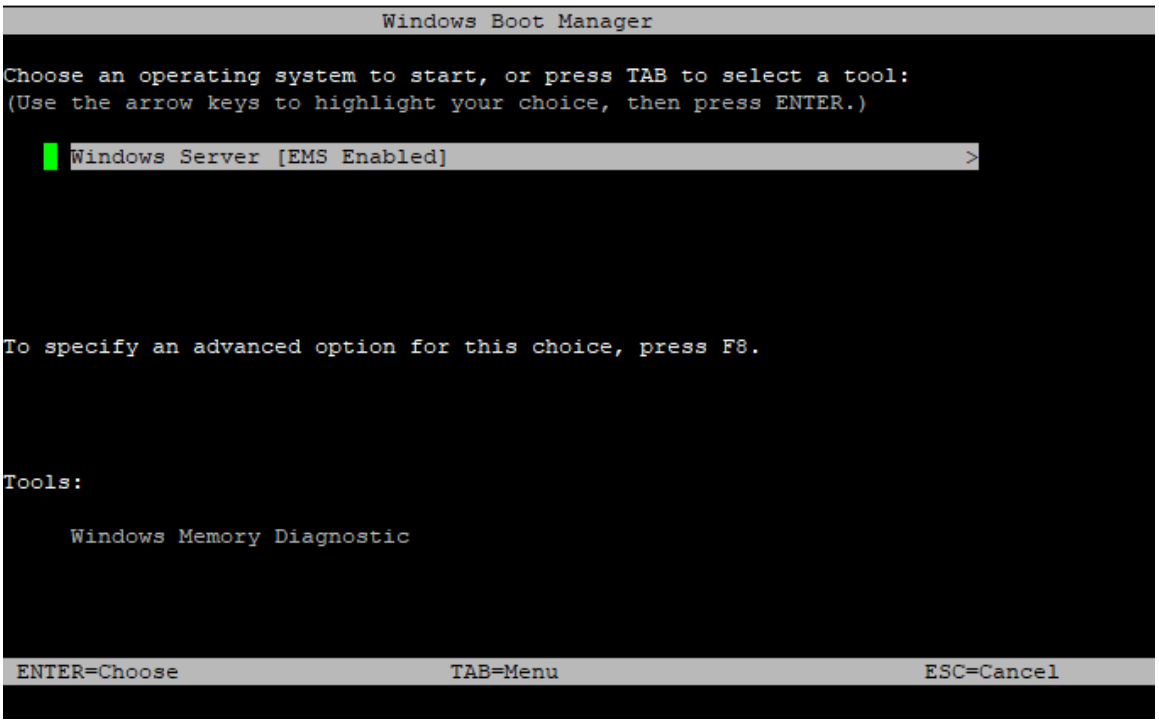
3. To create a command prompt channel (such as `cmd0001` or `cmd0002`), enter `cmd`, and then press **Enter**.
4. To view the command prompt channel, press **ESC**, and then press **TAB**.

5. To switch channels, press **ESC+TAB+channel number** together. For example, to switch to the `cmd0002` channel (if it has been created), press **ESC+TAB+2**.
6. Enter the credentials required by the command prompt channel.

The command prompt is the same full-featured command shell that you get on a desktop, but with the exception that it does not allow the reading of characters that were already output.

Built-in SAC commands

Beyond opening a command prompt channel, SAC provides built-in commands that you can run directly at the SAC> prompt for out-of-band administration. These commands do not require you to sign in. The following table lists the built-in commands available at the SAC> prompt. To display this list from within SAC, enter `?` or `help`. SAC commands are not case-sensitive.



Command	Description
`ch`	Lists all available channels. Enter `ch -?` for channel management help.
`cmd`	Creates a Windows command prompt channel. You must provide administrative credentials to use the channel.
`d`	Displays the current kernel log.

Command	Description
`f`	Toggles the `t` (tlist) output between showing processes only and showing both processes and threads.
`?` or `help`	Lists the available SAC commands.
`i`	Lists all network interfaces with their IP addresses.
`i <#> <ip> <subnet> <gateway>`	Sets the IP address, subnet mask, and gateway for the specified network interface number. Useful for restoring connectivity after a network misconfiguration locks you out of the instance.
`id`	Displays the instance identification information.
`k <pid>`	Ends the process with the specified process ID. Useful for stopping an unresponsive process.
`l <pid>`	Lowers the priority of the specified process to the lowest possible value.
`lock`	Locks access to command prompt channels.
`m <pid> <MB-allow>`	Limits the memory usage of the specified process to the specified number of megabytes.
`p`	Pauses the `t` (tlist) output after each screen of information.
`r <pid>`	Raises the priority of the specified process by one level.
`s`	Displays the current date and time. To set them, use `s mm/dd/yyyy hh:mm` .
`t`	Lists the running processes and threads (tlist).
`restart`	Restarts the instance immediately.
`shutdown`	Shuts down the instance immediately.

Command	Description
`crashdump`	Forces a stop error (crash) so the instance generates a memory dump for analysis. The instance must have crash dump enabled.

Use the boot menu

If the boot menu is enabled and you restart the instance after connecting through the serial console, the boot menu should appear as follows.

Boot menu commands

ENTER

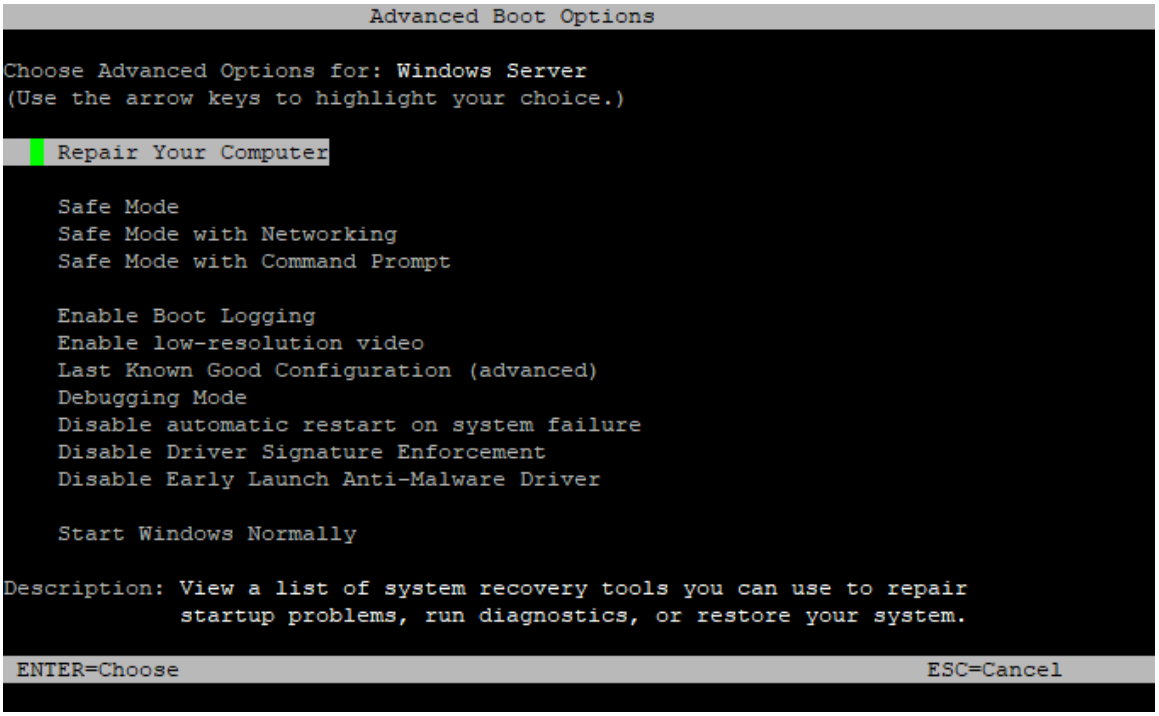
Starts the selected entry of the operating system.

TAB

Switches to the Tools menu.

ESC

Cancels and restarts the instance.



ESC followed by **8**

Equivalent to pressing **F8**. Shows advanced options for the selected item.

ESC key + **left arrow**

Goes back to the initial boot menu.

The ESC key alone does not take you back to the main menu because Windows is waiting to see if an escape sequence is in progress.

Known behaviors

- **SAC not appearing on bare metal instances** – If the SAC console does not appear when you connect to the serial console, SAC might be using the wrong serial port device. To re-enable SAC on a bare metal instance, see the bare metal instructions in Enable SAC and the boot menu.
- **Blank screen on connect** – When you connect to the serial console on a Windows instance with SAC enabled, you might see a blank screen instead of the SAC> prompt. Press **Enter** to display the SAC> prompt.
- **Unexpected output in system log** – If you enable SAC or the boot menu, the Amazon EC2 system log (available from the Amazon EC2 console or the `get-console-output` AWS Command Line Interface (AWS CLI) command) might contain output from SAC or the boot

menu. You might see output from SAC such as `SAC> EVENT: The CMD command is now available.` or ANSI escape sequences such as `[2J[1;1H[0m[37;40m` from the boot menu. This output is expected behavior.

Disable SAC and the boot menu

If you enable SAC and the boot menu, you can disable these features later.

Use one of the following methods to disable SAC and the boot menu on an instance.

PowerShell

To disable SAC and the boot menu on a Windows instance

1. Connect to your instance and perform the following steps from an elevated PowerShell command line.
2. First disable the boot menu by changing the value to no.

```
bcdedit /set '{bootmgr}' displaybootmenu no
```

3. Then disable SAC by changing the value to `off`.

```
bcdedit /ems '{current}' off
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Command prompt

To disable SAC and the boot menu on a Windows instance

1. Connect to your instance and perform the following steps from the command prompt.
2. First disable the boot menu by changing the value to no.

```
bcdedit /set {bootmgr} displaybootmenu no
```

3. Then disable SAC by changing the value to `off`.

```
bcdedit /ems {current} off
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Reset the Windows administrator password for an Amazon EC2 Windows instance

If you are no longer able to connect to your Amazon EC2 Windows instance because the Windows administrator password is lost or expired, you can reset the password.

> **Note**
>
> There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see Reset passwords and SSH keys on EC2 instances in the *AWS Systems Manager User Guide*.

The manual methods to reset the administrator password use EC2Launch v2, EC2Config, or EC2Launch.

- For all supported Windows AMIs that include the EC2Launch v2 agent, use EC2Launch v2.
- For Windows AMIs before Windows Server 2016, use the EC2Config service.
- For Windows Server 2016 and later AMIs, use the EC2Launch service.

These procedures also describe how to connect to an instance if you lost the key pair that was used to create the instance. Amazon EC2 uses a public key to encrypt a piece of data, such as a password, and a private key to decrypt the data. The public and private keys are known as a *key pair*. With Windows instances, you use a key pair to obtain the administrator password and then log in using RDP.

> **Note**
>
> If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see Use EC2Rescue for Windows Server with Systems Manager Run Command.

Contents

- Reset Windows admin password for EC2 instance using EC2Launch v2
- Reset Windows admin password for EC2 instance using EC2Launch
- Reset Windows admin password for EC2 instance using EC2Config

Reset Windows admin password for EC2 instance using EC2Launch v2

If you have lost your Windows administrator password and are using a supported Windows AMI that includes the EC2Launch v2 agent, you can use EC2Launch v2 to generate a new password.

If you are using a Windows Server 2016 or later AMI that does not include the EC2Launch v2 agent, see Reset Windows admin password for EC2 instance using EC2Launch.

If you are using a Windows Server AMI earlier than Windows Server 2016 that does not include the EC2Launch v2 agent, see Reset Windows admin password for EC2 instance using EC2Config.

> **Note**
>
> If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see Use EC2Rescue for Windows Server with Systems Manager Run Command.

> **Note**
>
> There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see Reset passwords and SSH keys on EC2 instances in the *AWS Systems Manager User Guide*.

To reset your Windows administrator password using EC2Launch v2, you need to do the following:

- Step 1: Verify that the EC2Launch v2 agent is running
- Step 2: Detach the root volume from the instance
- Step 3: Attach the volume to a temporary instance
- Step 4: Delete the .run-once file
- Step 5: Restart the original instance

Step 1: Verify that the EC2Launch v2 agent is running

Before you attempt to reset the administrator password, verify that the EC2Launch v2 agent is installed and running. You use the EC2Launch v2 agent to reset the administrator password later in this section.

To verify that the EC2Launch v2 agent is running

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances** and then select the instance that requires a password reset. This instance is referred to as the *original* instance in this procedure.
3. Choose **Actions**, **Monitor and troubleshoot**, **Get system log**.
4. Locate the EC2 Launch entry, for example, **Launch: EC2Launch v2 service v2.0.124**. If you see this entry, the EC2Launch v2 service is running.

   If the system log output is empty, or if the EC2Launch v2 agent is not running, troubleshoot the instance using the Instance Console Screenshot service. For more information, see Capture a screenshot of an unreachable instance.

Step 2: Detach the root volume from the instance

You can't use EC2Launch v2 to reset an administrator password if the volume on which the password is stored is attached to an instance as the root volume. You must detach the volume from the original instance before you can attach it to a temporary instance as a secondary volume.

To detach the root volume from the instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that requires a password reset and choose **Instance state**, **Stop instance**. After the status of the instance changes to **Stopped**, continue with the next step.
4. (Optional) If you have the private key that you specified when you launched this instance, continue with the next step. Otherwise, use the following steps to replace the instance with a new instance that you launch with a new key pair.

    a. Create a new key pair using the Amazon EC2 console. To give your new key pair the same name as the one for which you lost the private key, you must first delete the existing key pair.

    b. Select the instance to replace. Note the instance type, VPC, subnet, security group, and IAM role of the instance.

    c. With the instance selected, choose **Actions**, **Image and templates**, **Create image**. Type a name and a description for the image and choose **Create image**.

    d. In the navigation pane, choose **AMIs**. Wait for the image status to change to **available**. Then, select the image and choose **Launch instance from AMI**.

    e. Complete the fields to launch an instance, making sure to select the same instance type, VPC, subnet, security group, and IAM role as the instance to replace, and then choose **Launch instance**.

    f. When prompted, choose the key pair that you created for the new instance, and then choose **Launch instance**.

    g. (Optional) If the original instance has an associated Elastic IP address, transfer it to the new instance. If the original instance has EBS volumes in addition to the root volume, transfer them to the new instance.

5. Detach the root volume from the original instance as follows:

a. Select the original instance and choose the **Storage** tab. Note the name of the root device under **Root device name**. Find the volume with this device name under **Block devices**, and note the volume ID.

b. In the navigation pane, choose **Volumes**.

c. In the list of volumes, select the volume that you noted as the root device, and choose **Actions**, **Detach Volume**. After the volume status changes to **available**, continue with the next step.

6. If you created a new instance to replace your original instance, you can terminate the original instance now. It's no longer needed. For the remainder of this procedure, all references to the original instance apply to the new instance that you created.

Step 3: Attach the volume to a temporary instance

Next, launch a temporary instance and attach the volume to it as a secondary volume. This is the instance you use to modify the configuration file.

To launch a temporary instance and attach the volume

1. Launch the temporary instance as follows:

a. In the navigation pane, choose **Instances**, choose **Launch instances**, and then select an AMI.

> **Important**
>
> To avoid disk signature collisions, you must select an AMI for a different version of Windows. For example, if the original instance runs Windows Server 2019, launch the temporary instance using the base AMI for Windows Server 2016.

b. Leave the default instance type and choose **Next: Configure Instance Details**.

c. On the **Configure Instance Details** page, for **Subnet**, select the same Availability Zone as the original instance and choose **Review and Launch**.

> **Important**
>
> The temporary instance must be in the same Availability Zone as the original instance. If your temporary instance is in a different Availability Zone, you can't attach the original instance's root volume to it.

d. On the **Review Instance Launch** page, choose **Launch**.

e. When prompted, create a new key pair, download it to a safe location on your computer, and then choose **Launch Instances**.

2. Attach the volume to the temporary instance as a secondary volume as follows:

a. In the navigation pane, choose **Volumes**, select the volume that you detached from the original instance, and then choose **Actions**, **Attach Volume**.

b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your temporary instance and select the instance from the list.

c. For **Device**, type **xvdf** (if it isn't already there), and choose **Attach**.

Step 4: Delete the .run-once file

You must now delete the `.run-once` file from the offline volume attached to the instance. This directs EC2Launch v2 to run all tasks with a frequency of `once`, which includes setting the administrator password. The file path in the secondary volume that you attached will be similar to `D:\ProgramData\Amazon\EC2Launch\state\.run-once`.

To delete the .run-once file

1. Open the **Disk Management** utility, and bring the drive online using these instructions: Make an Amazon EBS volume available for use.
2. Locate the `.run-once` file in the disk you brought online.
3. Delete the .run-once file.

> **Important**
>
> Any scripts set to run once will be triggered by this action.

Step 5: Restart the original instance

After you have deleted the `.run-once` file, reattach the volume to the original instance as the root volume and connect to the instance using its key pair to retrieve the administrator password.

1. Reattach the volume to the original instance as follows:
   a. In the navigation pane, choose **Volumes**, select the volume that you detached from the temporary instance, and then choose **Actions**, **Attach Volume**.
   b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your original instance and then select the instance.
   c. For **Device**, type **`/dev/sda1`**.
   d. Choose **Attach**. After the volume status changes to `in-use`, continue to the next step.
2. In the navigation pane, choose **Instances**. Select the original instance and choose **Instance state**, **Start instance**. After the instance state changes to `Running`, continue to the next step.
3. Retrieve your new Windows administrator password using the private key for the new key pair and connect to the instance. For more information, see Connect to your Windows instance using RDP.

   > **Important**
   >
   > The instance gets a new public IP address after you stop and start it. Make sure to connect to the instance using its current public DNS name. For more information, see Amazon EC2 instance state changes.

4. (Optional) If you have no further use for the temporary instance, you can terminate it. Select the temporary instance, and choose **Instance State**, **Terminate instance**.

Reset Windows admin password for EC2 instance using EC2Launch

If you have lost your Windows administrator password and are using a Windows Server 2016 or later AMI, you can use the EC2Rescue tool, which uses the EC2Launch service to generate a new password.

If you are using a Windows Server 2016 or later AMI that does not include the EC2Launch v2 agent, you can use EC2Launch v2 to generate a new password.

If you are using a Windows Server AMI earlier than Windows Server 2016, see Reset Windows admin password for EC2 instance using EC2Config.

Warning

When you stop an instance, the data on instance store volumes is lost. To preserve this data, back it up to persistent storage.

Note

If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see Use EC2Rescue for Windows Server with Systems Manager Run Command.

Note

There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see Reset passwords and SSH keys on EC2 instances in the *AWS Systems Manager User Guide*.

To reset your Windows administrator password using EC2Launch, you need to do the following:

- Step 1: Detach the root volume from the instance
- Step 2: Attach the volume to a temporary instance
- Step 3: Reset the administrator password
- Step 4: Restart the original instance

Step 1: Detach the root volume from the instance

You can't use EC2Launch to reset an administrator password if the volume on which the password is stored is attached to an instance as the root volume. You must detach the volume from the original instance before you can attach it to a temporary instance as a secondary volume.

To detach the root volume from the instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that requires a password reset and choose **Instance state**, **Stop instance**. After the status of the instance changes to **Stopped**, continue with the next step.
4. (Optional) If you have the private key that you specified when you launched this instance, continue with the next step. Otherwise, use the following steps to replace the instance with a new instance that you launch with a new key pair.

    a. Create a new key pair using the Amazon EC2 console. To give your new key pair the same name as the one for which you lost the private key, you must first delete the existing key pair.

    b. Select the instance to replace. Note the instance type, VPC, subnet, security group, and IAM role of the instance.

    c. With the instance selected, choose **Actions**, **Image and templates**, **Create image**. Type a name and a description for the image and choose **Create image**.

    d. In the navigation pane, choose **AMIs**. Wait for the image status to change to **available**. Then, select the image and choose **Launch instance from AMI**.

    e. Complete the fields to launch an instance, making sure to select the same instance type, VPC, subnet, security group, and IAM role as the instance to replace, and then choose **Launch instance**.

    f. When prompted, choose the key pair that you created for the new instance, and then choose **Launch instance**.

    g. (Optional) If the original instance has an associated Elastic IP address, transfer it to the new instance. If the original instance has EBS volumes in addition to the root volume, transfer them to the new instance.

5. Detach the root volume from the original instance as follows:

    a. Select the original instance and choose the **Storage** tab. Note the name of the root device under **Root device name**. Find the volume with this device name under **Block devices**, and note the volume ID.

    b. In the navigation pane, choose **Volumes**.

c. In the list of volumes, select the volume that you noted as the root device, and choose **Actions**, **Detach Volume**. After the volume status changes to **available**, continue with the next step.

6. If you created a new instance to replace your original instance, you can terminate the original instance now. It's no longer needed. For the remainder of this procedure, all references to the original instance apply to the new instance that you created.

Step 2: Attach the volume to a temporary instance

Next, launch a temporary instance and attach the volume to it as a secondary volume. This is the instance you use to run EC2Launch.

To launch a temporary instance and attach the volume

1. Launch the temporary instance as follows:

   a. In the navigation pane, choose **Instances**, choose **Launch instances**, and then select an AMI.

   > **Important**
   >
   > To avoid disk signature collisions, you must select an AMI for a different version of Windows. For example, if the original instance runs Windows Server 2019, launch the temporary instance using the base AMI for Windows Server 2016.

   b. Leave the default instance type and choose **Next: Configure Instance Details**.

   c. On the **Configure Instance Details** page, for **Subnet**, select the same Availability Zone as the original instance and choose **Review and Launch**.

   > **Important**
   >
   > The temporary instance must be in the same Availability Zone as the original instance. If your temporary instance is in a different Availability Zone, you can't attach the original instance's root volume to it.

   d. On the **Review Instance Launch** page, choose **Launch**.

   e. When prompted, create a new key pair, download it to a safe location on your computer, and then choose **Launch Instances**.

2. Attach the volume to the temporary instance as a secondary volume as follows:

   a. In the navigation pane, choose **Volumes**, select the volume that you detached from the original instance, and then choose **Actions**, **Attach Volume**.

   b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your temporary instance and select the instance from the list.

   c. For **Device**, type **xvdf** (if it isn't already there), and choose **Attach**.

Step 3: Reset the administrator password

Next, connect to the temporary instance and use EC2Launch to reset the administrator password.

To reset the administrator password

1. Connect to the temporary instance and use the EC2Rescue for Windows Server tool on the instance to reset the administrator password as follows:

   a. Download the EC2Rescue for Windows Server zip file, extract the contents, and run **EC2Rescue.exe**.

   b. On the **License Agreement** screen, read the license agreement, and, if you accept the terms, choose **I Agree**.

   c. On the **Welcome to EC2Rescue for Windows Server** screen, choose **Next**.

   d. On the **Select mode** screen, choose **Offline instance**.

   e. On the **Select a disk** screen, select the **xvdf** device and choose **Next**.

   f. Confirm the disk selection and choose **Yes**.

   g. After the volume has loaded, choose **OK**.

   h. On the **Select Offline Instance Option** screen, choose **Diagnose and Rescue**.

   i. On the **Summary** screen, review the information and choose **Next**.

   j. On the **Detected possible issues** screen, select **Reset Administrator Password** and choose **Next**.

   k. On the **Confirm** screen, choose **Rescue**, **OK**.

   l. On the **Done** screen, choose **Finish**.

   m. Close the EC2Rescue for Windows Server tool, disconnect from the temporary instance, and then return to the Amazon EC2 console.

2. Detach the secondary (`xvdf`) volume from the temporary instance as follows:

a. In the navigation pane, choose **Instances** and select the temporary instance.

b. On the **Storage** tab for the temporary instance, note the ID of the EBS volume listed as **xvdf**.

c. In the navigation pane, choose **Volumes**.

d. In the list of volumes, select the volume noted in the previous step, and choose **Actions**, **Detach Volume**. After the volume status changes to **available**, continue with the next step.

Step 4: Restart the original instance

After you have reset the administrator password using EC2Launch, reattach the volume to the original instance as the root volume and connect to the instance using its key pair to retrieve the administrator password.

To restart the original instance

1. Reattach the volume to the original instance as follows:

   a. In the navigation pane, choose **Volumes**, select the volume that you detached from the temporary instance, and then choose **Actions**, **Attach Volume**.

   b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your original instance and then select the instance.

   c. For **Device**, type **`/dev/sda1`**.

   d. Choose **Attach**. After the volume status changes to `in-use`, continue to the next step.

2. In the navigation pane, choose **Instances**. Select the original instance and choose **Instance state**, **Start instance**. After the instance state changes to `Running`, continue to the next step.

3. Retrieve your new Windows administrator password using the private key for the new key pair and connect to the instance. For more information, see Connect to your Windows instance using RDP.

4. (Optional) If you have no further use for the temporary instance, you can terminate it. Select the temporary instance, and choose **Instance State**, **Terminate instance**.

Reset Windows admin password for EC2 instance using EC2Config

If you have lost your Windows administrator password and are using a Windows AMI before Windows Server 2016, you can use the EC2Config agent to generate a new password.

If you are using a Windows Server 2016 or later AMI, see Reset Windows admin password for EC2 instance using EC2Launch or, you can use the EC2Rescue tool, which uses the EC2Launch service to generate a new password.

Note

If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see Use EC2Rescue for Windows Server with Systems Manager Run Command.

Note

There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see Reset passwords and SSH keys on EC2 instances in the *AWS Systems Manager User Guide*.

To reset your Windows administrator password using EC2Config, you need to do the following:

- Step 1: Verify that the EC2Config service is running
- Step 2: Detach the root volume from the instance
- Step 3: Attach the volume to a temporary instance
- Step 4: Modify the configuration file
- Step 5: Restart the original instance

Step 1: Verify that the EC2Config service is running

Before you attempt to reset the administrator password, verify that the EC2Config service is installed and running. You use the EC2Config service to reset the administrator password later in this section.

To verify that the EC2Config service is running

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances** and then select the instance that requires a password reset. This instance is referred to as the *original* instance in this procedure.
3. Choose **Actions**, **Monitor and troubleshoot**, **Get system log**.
4. Locate the EC2 Agent entry, for example, **EC2 Agent: Ec2Config service v3.18.1118**. If you see this entry, the EC2Config service is running.

   If the system log output is empty, or if the EC2Config service is not running, troubleshoot the instance using the Instance Console Screenshot service. For more information, see Capture a screenshot of an unreachable instance.

Step 2: Detach the root volume from the instance

You can't use EC2Config to reset an administrator password if the volume on which the password is stored is attached to an instance as the root volume. You must detach the volume from the original instance before you can attach it to a temporary instance as a secondary volume.

To detach the root volume from the instance

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that requires a password reset and choose **Instance state**, **Stop instance**. After the status of the instance changes to **Stopped**, continue with the next step.
4. (Optional) If you have the private key that you specified when you launched this instance, continue with the next step. Otherwise, use the following steps to replace the instance with a new instance that you launch with a new key pair.

   a. Create a new key pair using the Amazon EC2 console. To give your new key pair the same name as the one for which you lost the private key, you must first delete the existing key pair.

b. Select the instance to replace. Note the instance type, VPC, subnet, security group, and IAM role of the instance.

c. With the instance selected, choose **Actions**, **Image and templates**, **Create image**. Type a name and a description for the image and choose **Create image**.

d. In the navigation pane, choose **AMIs**. Wait for the image status to change to **available**. Then, select the image and choose **Launch instance from AMI**.

e. Complete the fields to launch an instance, making sure to select the same instance type, VPC, subnet, security group, and IAM role as the instance to replace, and then choose **Launch instance**.

f. When prompted, choose the key pair that you created for the new instance, and then choose **Launch instance**.

g. (Optional) If the original instance has an associated Elastic IP address, transfer it to the new instance. If the original instance has EBS volumes in addition to the root volume, transfer them to the new instance.

5. Detach the root volume from the original instance as follows:

   a. Select the original instance and choose the **Storage** tab. Note the name of the root device under **Root device name**. Find the volume with this device name under **Block devices**, and note the volume ID.

   b. In the navigation pane, choose **Volumes**.

   c. In the list of volumes, select the volume that you noted as the root device, and choose **Actions**, **Detach Volume**. After the volume status changes to **available**, continue with the next step.

6. If you created a new instance to replace your original instance, you can terminate the original instance now. It's no longer needed. For the remainder of this procedure, all references to the original instance apply to the new instance that you created.

Step 3: Attach the volume to a temporary instance

Next, launch a temporary instance and attach the volume to it as a secondary volume. This is the instance you use to modify the configuration file.

To launch a temporary instance and attach the volume

1. Launch the temporary instance as follows:

a. In the navigation pane, choose **Instances**, choose **Launch instances**, and then select an AMI.

> **Important**
>
> To avoid disk signature collisions, you must select an AMI for a different version of Windows. For example, if the original instance runs Windows Server 2019, launch the temporary instance using the base AMI for Windows Server 2016.

b. Leave the default instance type and choose **Next: Configure Instance Details**.

c. On the **Configure Instance Details** page, for **Subnet**, select the same Availability Zone as the original instance and choose **Review and Launch**.

> **Important**
>
> The temporary instance must be in the same Availability Zone as the original instance. If your temporary instance is in a different Availability Zone, you can't attach the original instance's root volume to it.

d. On the **Review Instance Launch** page, choose **Launch**.

e. When prompted, create a new key pair, download it to a safe location on your computer, and then choose **Launch Instances**.

2. Attach the volume to the temporary instance as a secondary volume as follows:

a. In the navigation pane, choose **Volumes**, select the volume that you detached from the original instance, and then choose **Actions**, **Attach Volume**.

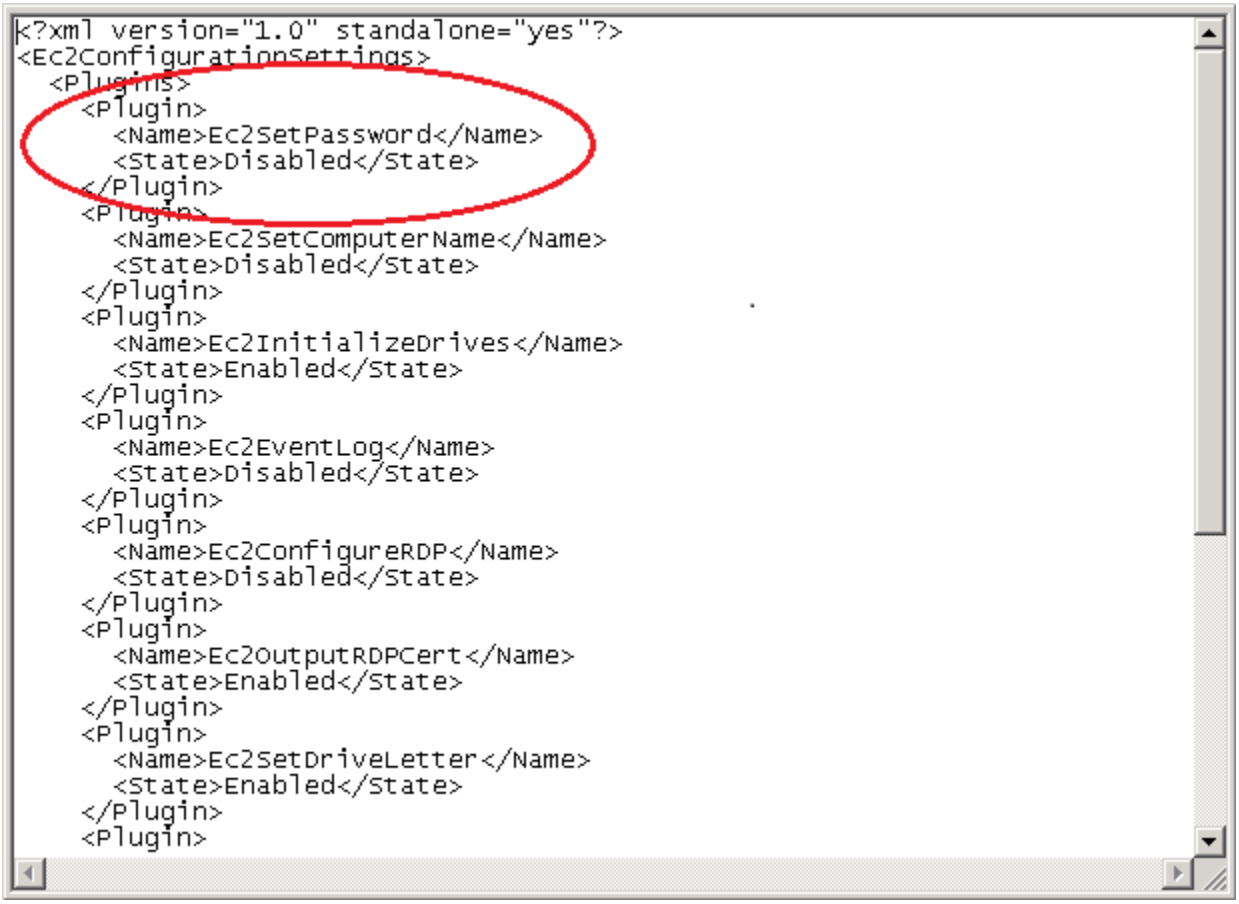
b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your temporary instance and select the instance from the list.

c. For **Device**, type **`xvdf`** (if it isn't already there), and choose **Attach**.

Step 4: Modify the configuration file

After you have attached the volume to the temporary instance as a secondary volume, modify the `Ec2SetPassword` plugin in the configuration file.

To modify the configuration file



1. From the temporary instance, modify the configuration file on the secondary volume as follows:

   a. Launch and connect to the temporary instance.

   b. Use the following instructions to bring the drive online: Make an Amazon EBS volume available for use.

   c. Navigate to the secondary volume, and open `\Program Files\Amazon \Ec2ConfigService\Settings\config.xml` using a text editor, such as Notepad.

   d. At the top of the file, find the plugin with the name `Ec2SetPassword`, as shown in the screenshot. Change the state from `Disabled` to `Enabled` and save the file.

2. After you have modified the configuration file, detach the secondary volume from the temporary instance as follows:

   a. Using the **Disk Management** utility, bring the volume offline.

   b. Disconnect from the temporary instance and return to the Amazon EC2 console.

c. In the navigation pane, choose **Volumes**, select the volume, and then choose **Actions**, **Detach Volume**. After the volume's status changes to **available**, continue with the next step.

Step 5: Restart the original instance

After you have modified the configuration file, reattach the volume to the original instance as the root volume and connect to the instance using its key pair to retrieve the administrator password.

1. Reattach the volume to the original instance as follows:

   a. In the navigation pane, choose **Volumes**, select the volume that you detached from the temporary instance, and then choose **Actions**, **Attach Volume**.

   b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your original instance and then select the instance.

   c. For **Device**, type **`/dev/sda1`**.

   d. Choose **Attach**. After the volume status changes to `in-use`, continue to the next step.

2. In the navigation pane, choose **Instances**. Select the original instance and choose **Instance state**, **Start instance**. After the instance state changes to `Running`, continue to the next step.

3. Retrieve your new Windows administrator password using the private key for the new key pair and connect to the instance. For more information, see Connect to your Windows instance using RDP.

   > **Important**
   >
   > The instance gets a new public IP address after you stop and start it. Make sure to connect to the instance using its current public DNS name. For more information, see Amazon EC2 instance state changes.

4. (Optional) If you have no further use for the temporary instance, you can terminate it. Select the temporary instance, and choose **Instance State**, **Terminate instance**.

Troubleshoot Sysprep issues with Amazon EC2 Windows instances

If you experience problems or receive error messages during image preparations, review the following logs. Log location varies depending on whether you are running EC2Config, EC2Launch v1, or EC2Launch v2 with Sysprep.

- `%WINDIR%\Panther\Unattendgc` (EC2Config, EC2Launch v1, and EC2Launch v2)
- `%WINDIR%\System32\Sysprep\Panther` (EC2Config, EC2Launch v1, and EC2Launch v2)
- `C:\Program Files\Amazon\Ec2ConfigService\Logs\Ec2ConfigLog.txt` (EC2Config only)
- `C:\ProgramData\Amazon\Ec2Config\Logs` (EC2Config only)
- `C:\ProgramData\Amazon\EC2-Windows\Launch\Log\EC2Launch.log` (EC2Launch v1 only)
- `%ProgramData%\Amazon\EC2Launch\log\agent.log` (EC2Launch v2 only)

If you receive an error message during image preparation with Sysprep, the OS might not be reachable. To review the log files, you must stop the instance, attach its root volume to another healthy instance as a secondary volume, and then review the logs mentioned earlier on the secondary volume. For more information about the purpose of the log files by name, see Windows Setup-Related Log Files in the Microsoft documentation.

If you locate errors in the Unattendgc log file, use the Microsoft Error Lookup Tool to get more details about the error. The following issue reported in the Unattendgc log file is typically the result of one or more corrupted user profiles on the instance:

```
Error [Shell Unattend] _FindLatestProfile failed (0x80070003) [gle=0x00000003]
Error [Shell Unattend] CopyProfile failed (0x80070003) [gle=0x00000003]
```

There are two options for resolving this issue:

Option 1

Use Regedit on the instance to search for the following key. Verify that there are no profile registry keys for a deleted user.

```
[HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion
\ProfileList\
```

Option 2

1. Edit the relevant file, as follows:
   - Windows Server 2012 R2 and earlier – Edit the EC2Config answer file (`C:\Program Files\Amazon\Ec2ConfigService\sysprep2008.xml`).
   - Windows Server 2016 and 2019 – Edit the unattend.xml answer file (`C:\ProgramData\Amazon\EC2-Windows\Launch\Sysprep\Unattend.xml`).
   - Windows Server 2022 – Edit the unattend.xml answer file (`C:\ProgramData\Amazon\EC2Launch\sysprep\unattend.xml`).
2. Change `<CopyProfile>true</CopyProfile>` to `<CopyProfile>false</CopyProfile>`.
3. Run Sysprep again. Note that this configuration change will delete the built-in administrator user profile after Sysprep completes.

Troubleshoot impaired Amazon EC2 Linux instance using EC2Rescue

EC2Rescue for Linux is an easy-to-use, open-source tool that can be run on an Amazon EC2 Linux instance to diagnose, troubleshoot, and remediate common issues using its library of over 100 *modules*. Modules are YAML files that contain either a BASH or a Python script and the necessary metadata.

Some generalized use cases for EC2Rescue for Linux instances include:

- Gathering syslog and package manager logs
- Collecting resource utilization data
- Diagnosing and remediating known problematic kernel parameters and common OpenSSH issues

> **Note**
>
> The `AWSSupport-TroubleshootSSH` AWS Systems Manager Automation runbook installs EC2Rescue for Linux and then uses the tool to check or attempt to fix common issues that prevent an SSH connection to a Linux instance. For more information, see AWSSupport-TroubleshootSSH.

If you are using a Windows instance, see the section called "EC2Rescue for Windows instances".

Topics

- Install EC2Rescue on an Amazon EC2 Linux instance
- Run EC2Rescue commands on an Amazon EC2 Linux instance
- Develop EC2Rescue modules for Amazon EC2 Linux instances

Install EC2Rescue on an Amazon EC2 Linux instance

The EC2Rescue for Linux tool can be installed on an Amazon EC2 Linux instance that meets the following prerequisites.

Prerequisites

- Supported operating systems:
  - Amazon Linux 2
  - Amazon Linux 2016.09+
  - SUSE Linux Enterprise Server 12+
  - RHEL 7+
  - Ubuntu 16.04+
- Software requirements:
  - Python 2.7.9+ or 3.2+

Install EC2Rescue

The `AWSSupport-TroubleshootSSH` runbook installs EC2Rescue for Linux and then uses the tool to check or attempt to fix common issues that prevent a remote connection to a Linux machine through SSH. For more information, and to run this automation, see Support-TroubleshootSSH.

If your system has the required Python version, you can install the standard build. Otherwise, you can install the bundled build, which includes a minimal copy of Python.

To install the standard build

1. From a working Linux instance, download the EC2Rescue for Linux tool:
2. (*Optional*) Verify the signature of the EC2Rescue for Linux installation file. For more information, see (Optional) Verify the signature of EC2Rescue for Linux.
3. Download the sha256 hash file:
4. Verify the integrity of the tarball:

```
sha256sum -c ec2rl.tgz.sha256
```

5. Unpack the tarball:

```
tar -xzvf ec2rl.tgz
```

6. Verify the installation by listing out the help file:

```
cd ec2rl-<version_number>
./ec2rl help
```

To install the bundled build

For a link to the download and a list of limitations, see EC2Rescue for Linux on github.

(Optional) Verify the signature of EC2Rescue for Linux

The following is the recommended process of verifying the validity of the EC2Rescue for Linux package for Linux-based operating systems.

When you download an application from the internet, we recommend that you authenticate the identity of the software publisher and check that the application has not been altered or corrupted

after it was published. This protects you from installing a version of the application that contains a virus or other malicious code.

If, after running the steps in this topic, you determine that the software for EC2Rescue for Linux is altered or corrupted, do not run the installation file. Instead, contact Amazon Web Services.

EC2Rescue for Linux files for Linux-based operating systems are signed using GnuPG, an open-source implementation of the Pretty Good Privacy (OpenPGP) standard for secure digital signatures. GnuPG (also known as GPG) provides authentication and integrity checking through a digital signature. AWS publishes a public key and signatures that you can use to verify the downloaded EC2Rescue for Linux package. For more information about PGP and GnuPG (GPG), see https://www.gnupg.org/.

The first step is to establish trust with the software publisher. Download the public key of the software publisher, check that the owner of the public key is who they claim to be, and then add the public key to your keyring. Your keyring is a collection of known public keys. After you establish the authenticity of the public key, you can use it to verify the signature of the application.

Tasks

- Authenticate and import the public key
- Verify the signature of the package

Authenticate and import the public key

The next step in the process is to authenticate the EC2Rescue for Linux public key and add it as a trusted key in your GPG keyring.

To authenticate and import the EC2Rescue for Linux public key

1. At a command prompt, use the following command to obtain a copy of our public GPG build key:
2. At a command prompt in the directory where you saved `ec2rl.key`, use the following command to import the EC2Rescue for Linux public key into your keyring:

   ```
   gpg2 --import ec2rl.key
   ```

   The command returns results similar to the following:

   ```
   gpg: /home/ec2-user/.gnupg/trustdb.gpg: trustdb created
   ```

```
gpg: key 2FAE2A1C: public key "ec2autodiag@amazon.com <EC2 Rescue for Linux>"
 imported
gpg: Total number processed: 1
gpg:               imported: 1  (RSA: 1)
```

> **Tip**
>
> If you see an error stating that the command cannot be found, install the GnuPG utility with `apt-get install gnupg2` (Debian-based Linux) or `yum install gnupg2` (Red Hat- based Linux).

Verify the signature of the package

After you've installed the GPG tools, authenticated and imported the EC2Rescue for Linux public key, and verified that the EC2Rescue for Linux public key is trusted, you are ready to verify the signature of the EC2Rescue for Linux installation script.

To verify the EC2Rescue for Linux installation script signature

1. At a command prompt, run the following command to download the signature file for the installation script:
2. Verify the signature by running the following command at a command prompt in the directory where you saved `ec2rl.tgz.sig` and the EC2Rescue for Linux installation file. Both files must be present.

   ```
   gpg2 --verify ./ec2rl.tgz.sig
   ```

   The output should look something like the following:

   ```
   gpg: Signature made Thu 12 Jul 2018 01:57:51 AM UTC using RSA key ID 6991ED45
   gpg: Good signature from "ec2autodiag@amazon.com <EC2 Rescue for Linux>"
   gpg: WARNING: This key is not certified with a trusted signature!
   gpg:          There is no indication that the signature belongs to the owner.
   Primary key fingerprint: E528 BCC9 0DBF 5AFA 0F6C  C36A F780 4843 2FAE 2A1C
        Subkey fingerprint: 966B 0D27 85E9 AEEC 1146  7A9D 8851 1153 6991 ED45
   ```

If the output contains the phrase `Good signature from "ec2autodiag@amazon.com <EC2 Rescue for Linux>"`, it means that the signature has successfully been verified, and you can proceed to run the EC2Rescue for Linux installation script.

If the output includes the phrase `BAD signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and do not run the installation file that you downloaded previously.

The following are details about the warnings that you might see:

- **WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.** This refers to your personal level of trust in your belief that you possess an authentic public key for EC2Rescue for Linux. In an ideal world, you would visit an Amazon Web Services office and receive the key in person. However, more often you download it from a website. In this case, the website is an Amazon Web Services website.
- **gpg2: no ultimately trusted keys found.** This means that the specific key is not "ultimately trusted" by you (or by other people whom you trust).

For more information, see https://www.gnupg.org/.

Run EC2Rescue commands on an Amazon EC2 Linux instance

EC2Rescue is a command line tool. After you have installed EC2Rescue on your Linux instance, you can get general help on how to use the tool by running `./ec2rl help`. You can view the available modules by running `./ec2rl list`, and you can get help on a specific module by running `./ec2rl help` *`module_name`*.

The following are common tasks you can perform to get started using this tool.

Tasks

- Run EC2Rescue modules
- Upload the EC2Rescue module results
- Create backups of an Amazon EC2 Linux instance

Run EC2Rescue modules

To run all EC2Rescue modules

Use the **./ec2rl run** command without specifying any additional parameters. Some modules require root access. If you are not a root user, use **sudo** when you run the command.

```
./ec2rl run
```

To run a specific EC2Rescue module

Use the **./ec2rl run** command and for `--only-modules`, specify the name of the module to run. Some modules require *arguments* to use them.

```
./ec2rl run --only-modules=module_name --arguments
```

For example, to run the **dig** module to query the `amazon.com` domain, use the following command.

```
./ec2rl run --only-modules=dig --domain=amazon.com
```

To view the results of an EC2Rescue module

Run the module then view the log file in `cat /var/tmp/ec2rl/`*`logfile_location`*. For example, the log file for the **dig** module can be found in the following location:

```
cat /var/tmp/ec2rl/timestamp/mod_out/run/dig.log
```

Upload the EC2Rescue module results

If Support has requested the results for a EC2Rescue module, you can upload the log file using the EC2Rescue tool. You can upload the results either to a location provided by Support or to an Amazon S3 bucket that you own.

To upload results to a location provided by Support

Use the **./ec2rl upload** command. For `--upload-directory`, specify the location of the log file. For `--support-url`, specify the URL provided by Support.

```
./ec2rl upload --upload-directory=/var/tmp/ec2rl/logfile_location --support-
url="url_provided_by_aws_support"
```

To upload results to an Amazon S3 bucket

Use the **./ec2rl upload** command. For `--upload-directory`, specify the location of the log file. For `--presigned-url`, specify a presigned URL for the S3 bucket. For more information about generating pre-signed URLs for Amazon S3, see Uploading Objects Using Pre-Signed URLs.

```
./ec2rl upload --upload-directory=/var/tmp/ec2rl/logfile_location --presigned-
url="presigned_s3_url"
```

Create backups of an Amazon EC2 Linux instance

You can use EC2Rescue to backup your Linux instance by creating an AMI or by creating snapshots of it's attached volumes.

To create an AMI

Use the `./ec2rl run` command and for --backup, specify `ami`.

```
./ec2rl run --backup=ami
```

To create multi-volume snapshots of all attached volumes

Use the `./ec2rl run` command and for --backup, specify `allvolumes`.

```
./ec2rl run --backup=allvolumes
```

To create a snapshot of a specific attached volume

Use the `./ec2rl run` command and for --backup, specify the ID of the volume to back up.

```
./ec2rl run --backup=vol-01234567890abcdef
```

Develop EC2Rescue modules for Amazon EC2 Linux instances

Modules are written in YAML, a data serialization standard. A module's YAML file consists of a single document, representing the module and its attributes.

Add module attributes

The following table lists the available module attributes.

Attribute	Description
name	The name of the module. The name should be less than or equal to 18 characters in length.
version	The version number of the module.
title	A short, descriptive title for the module. This value should be less than or equal to 50 characters in length.

helptext	The extended description of the module. Each line should be less than or equal to 75 characters in length. If the module consumes arguments, required or optional, include them in the helptext value.
	
	For example:
	
	`helptext: !!str |`
	`  Collect output from ps for system analysis`
	`  Consumes --times= for number of times to repeat`
	`  Consumes --period= for time period between repetition`

placement	The stage in which the module should be run. Supported values: • prediagnostic • run • postdiagnostic

Attribute	Description
language	The language that the module code is written in. Supported values: • bash • python **Note** Python code must be compatible with both Python 2.7.9+ and Python 3.2+.
remediation	Indicates whether the module supports remediation. Supported values are `True` or `False`. The module defaults to `False` if this is absent, making it an optional attribute for those modules that do not support remediation.
content	The entirety of the script code.
constraint	The name of the object containing the constraint values.
domain	A descriptor of how the module is grouped or classified. The set of included modules uses the following domains: • application • net • os • performance

Attribute	Description
class	A descriptor of the type of task performed by the module. The set of included modules uses the following classes: • collect (collects output from programs) • diagnose (pass/fail based on a set of criteria) • gather (copies files and writes to specific file)
distro	The list of Linux distributions that this module supports. The set of included modules uses the following distributions: • **alami** (Amazon Linux) • **rhel** • **ubuntu** • **suse**
required	The required arguments that the module is consuming from the CLI options.
optional	The optional arguments that the module can use.
software	The software executables used in the module. This attribute is intended to specify software that is not installed by default. The EC2Rescue for Linux logic ensures that these programs are present and executable before running the module.

Attribute	Description
package	The source software package for an executable. This attribute is intended to provide extended details on the package with the software, including a URL for downloading or getting further information.
sudo	Indicates whether root access is required to run the module. You do not need to implement sudo checks in the module script. If the value is true, then the EC2Rescue for Linux logic only runs the module when the executing user has root access.
perfimpact	Indicates whether the module can have significant performance impact upon the environment in which it is run. If the value is true and the `--perfimpact=true` argument is not present, then the module is skipped.
parallelexclusive	Specifies a program that requires mutual exclusivity. For example, all modules specifying "bpf" run in a serial manner.

Add environment variables

The following table lists the available environment variables.

Environment Variable	Description
`EC2RL_CALLPATH`	The path to `ec2rl.py`. This path can be used to locate the lib directory and use vendored Python modules.

Environment Variable	Description
EC2RL_WORKDIR	The main tmp directory for the diagnostic tool. Default value: /var/tmp/ec2rl .
EC2RL_RUNDIR	The directory where all output is stored. Default value: /var/tmp/ec2rl/<date&timestamp> .
EC2RL_GATHEREDDIR	The root directory for placing gathered module data. Default value:/var/tmp/ec2rl/<date&timestamp>/mod_out/gathered/ .
EC2RL_NET_DRIVER	The driver in use for the first, alphabetically ordered, non-virtual network interface on the instance. Examples: • xen_netfront • ixgbevf • ena
EC2RL_SUDO	True if EC2Rescue for Linux is running as root; otherwise, false.
EC2RL_VIRT_TYPE	The virtualization type as provided by the instance metadata. Examples: • default-hvm • default-paravirtual

Environment Variable	Description
EC2RL_INTERFACES	An enumerated list of interfaces on the system. The value is a string containing names, such as eth0, eth1, and so on. This is generated by the functions.bash and is only available for modules that have sourced it.

Use YAML syntax

The following should be noted when constructing your module YAML files:

- The triple hyphen (---) denotes the explicit start of a document.
- The !ec2rlcore.module.Module tag tells the YAML parser which constructor to call when creating the object from the data stream. You can find the constructor inside the module.py file.
- The !!str tag tells the YAML parser to not attempt to determine the type of data, and instead interpret the content as a string literal.
- The pipe character (|) tells the YAML parser that the value is a literal-style scalar. In this case, the parser includes all whitespace. This is important for modules because indentation and newline characters are kept.
- The YAML standard indent is two spaces, which can be seen in the following examples. Ensure that you maintain standard indentation (for example, four spaces for Python) for your script and then indent the entire content two spaces inside the module file.

Example modules

Example one (mod.d/ps.yaml):

```
--- !ec2rlcore.module.Module
# Module document. Translates directly into an almost-complete Module object
name: !!str ps
path: !!str
version: !!str 1.0
title: !!str Collect output from ps for system analysis
helptext: !!str |
```

```
  Collect output from ps for system analysis
  Requires --times= for number of times to repeat
  Requires --period= for time period between repetition
placement: !!str run
package:
  - !!str
language: !!str bash
content: !!str |
  #!/bin/bash
  error_trap()
  {
      printf "%0.s=" {1..80}
      echo -e "\nERROR: "$BASH_COMMAND" exited with an error on line ${BASH_LINENO[0]}"
      exit 0
  }
  trap error_trap ERR

  # read-in shared function
  source functions.bash
  echo "I will collect ps output from this $EC2RL_DISTRO box for $times times every
 $period seconds."
  for i in $(seq 1 $times); do
      ps auxww
      sleep $period
  done
constraint:
  requires_ec2: !!str False
  domain: !!str performance
  class: !!str collect
  distro: !!str alami ubuntu rhel suse
  required: !!str period times
  optional: !!str
  software: !!str
  sudo: !!str False
  perfimpact: !!str False
  parallelexclusive: !!str
```

Troubleshoot impaired Amazon EC2 Windows instance using EC2Rescue

EC2Rescue for Windows Server is an easy-to-use tool that you run on an Amazon EC2 Windows Server instance to diagnose and troubleshoot possible problems. It is valuable for collecting log

files and troubleshooting issues and also proactively searching for possible areas of concern. It can even examine Amazon EBS root volumes from other instances and collect relevant logs for troubleshooting Windows Server instances using that volume. The following are some common issues that EC2Rescue can address:

- Instance connectivity issues due to firewall, Remote Desktop Protocol (RDP), or network interface configuration
- Operating system boot issues due to a stop error, boot loop, or corrupted registry
- Issues that might need advanced log analysis and troubleshooting

EC2Rescue for Windows Server has two different modules:

- A **data collector module** that collects data from all different sources
- An **analyzer module** that parses the data collected against a series of predefined rules to identify issues and provide suggestions

The EC2Rescue for Windows Server tool only runs on Amazon EC2 instances running Windows Server 2012 and later. When the tool starts, it checks whether it is running on an Amazon EC2 instance.

> **Note**
>
> The `AWSSupport-ExecuteEC2Rescue` AWS Systems Manager Automation runbook uses the EC2Rescue tool to troubleshoot and, where possible, fix common connectivity issues with the specified EC2 instance. For more information, and to run this automation, see >AWSSupport-ExecuteEC2Rescue.

If you are using a Linux instance, see the section called “EC2Rescue for Linux instances”.

- Troubleshoot impaired Windows instance with EC2Rescue and Systems Manager

Troubleshoot impaired Windows instance with the EC2Rescue GUI

EC2Rescue for Windows Server can perform the following analysis on **offline instances**:

Option	Description
Diagnose and Rescue	EC2Rescue for Windows Server can detect and address issues with the following service settings: • System Time • **RealTimeisUniversal** - Detects whether the `RealTimeisUniversal` registry key is enabled. If disabled, Windows system time drifts when the timezone is set to a value other than UTC. • Windows Firewall • **Domain networks** - Detects whether this Windows Firewall profile is enabled or disabled. • **Private networks** - Detects whether this Windows Firewall profile is enabled or disabled. • **Guest or public networks** - Detects whether this Windows Firewall profile is enabled or disabled. • Remote Desktop • **Service Start** - Detects whether the Remote Desktop service is enabled. • **Remote Desktop Connections** - Detects whether this is enabled. • **TCP Port** - Detects which port the Remote Desktop service is listening on.

Option	Description
	• EC2Config (Windows Server 2012 R2 and earlier) • **Installation** - Detects which EC2Config version is installed. • **Service Start** - Detects whether the EC2Config service is enabled. • **Ec2SetPassword** - Generates a new administrator password. • **Ec2HandleUserData** - Allows you to run a user data script on the next boot of the instance. • EC2Launch (Windows Server 2016 and later) • **Installation** - Detects which EC2Launch version is installed. • **Ec2SetPassword** - Generates a new administrator password. • Network Interface • **DHCP Service Startup** - Detects whether the DHCP service is enabled. • **Ethernet detail** - Displays informati on about the network driver version, if detected. • **DHCP on Ethernet** - Detects whether DHCP is enabled. • Disk signature status • **Signature on disk** and **Signature on Boot Configuration Database (BCD)** - Detects whether the disk signature and the BCD signature are the same. If the values are different, EC2Rescue attempts

Option	Description
	to overwrite the disk signature with the signature on BCD.
Restore	Perform one of the following actions: • **Last Known Good Configuration** - Attempts to boot the instance into the last known bootable state. • **Restore registry from backup** - Restores the registry from `\Windows\System32\config\RegBack` .
Capture Logs	Allows you to capture logs on the instance for analysis.

EC2Rescue for Windows Server can collect the following data from **active and offline instances**:

Item	Description
Event Log	Collects application, system, and EC2Config event logs.
Registry	Collects `SYSTEM` and `SOFTWARE` hives.
Windows Update Log	Collects log files generated by Windows Update. **Note** In Windows Server 2016 and later, the log is collected in Event Tracing for Windows (ETW) format.
Sysprep Log	Collects log files generated by the Windows System Preparation tool.

Item	Description
Driver Setup Log	Collects Windows SetupAPI logs (`setupapi.dev.log` and `setupapi.setup.log`).
Boot Configuration	Collects `HKEY_LOCAL_MACHINE\BCD00000000` hive.
Memory Dump	Collects any memory dump files that exist on the instance.
EC2Config File	Collects log files generated by the EC2Config service.
EC2Launch File	Collects log files generated by the EC2Launch scripts.
SSM Agent File	Collects log files generated by SSM Agent and Patch Manager logs.
EC2 ElasticGPUs File	Collects event logs related to elastic GPUs.
ECS	Collects logs related to Amazon ECS.
CloudEndure	Collects log files related to CloudEndure Agent.
AWS Replication Agent for MGN or DRS Log Files	Collects log files related to AWS Transform MGN or AWS Elastic Disaster Recovery.

EC2Rescue for Windows Server can collect the following additional data from **active instances**:

Item	Description
System Information	Collects MSInfo32.
Group Policy Result	Collects a Group Policy report.

Analyze an offline instance

The **Offline Instance** option is useful for debugging boot issues with Windows instances.

To perform an action on an offline instance

1. You can run the following PowerShell command to download EC2Rescue without changing your Internet Explorer Enhanced Security Configuration (ESC):

   ```
   Invoke-WebRequest https://s3.amazonaws.com/ec2rescue/windows/EC2Rescue_latest.zip -
   OutFile $env:USERPROFILE\Desktop\EC2Rescue_latest.zip
   ```

   This command will download the EC2Rescue .zip file to the desktop of the currently logged in user.

   > **Note**
   >
   > If you receive an error when downloading the file, and you are using Windows Server 2016 or earlier, TLS 1.2 might need to be enabled for your PowerShell terminal. You can enable TLS 1.2 for the current PowerShell session with the following command and then try again:
   >
   > ```
   > [Net.ServicePointManager]::SecurityProtocol =
   >  [Net.SecurityProtocolType]::Tls12
   > ```

2. Stop the faulty instance, if it is not stopped already.
3. Detach the EBS root volume from the faulty instance and attach the volume to a working Windows instance that has EC2Rescue for Windows Server installed.
4. Run the EC2Rescue for Windows Server tool on the working instance and choose **Offline Instance**.
5. Select the disk of the newly mounted volume and choose **Next**.
6. Confirm the disk selection and choose **Yes**.
7. Choose the offline instance option to perform and choose **Next**.

The EC2Rescue for Windows Server tool scans the volume and collects troubleshooting information based on the selected log files.

Collect data from an active instance

You can collect logs and other data from an active instance.

To collect data from an active instance

1. Connect to your Windows instance.
2. You can run the following PowerShell command to download EC2Rescue without changing your Internet Explorer Enhanced Security Configuration (ESC):

   ```
   Invoke-WebRequest https://s3.amazonaws.com/ec2rescue/windows/EC2Rescue_latest.zip -
   OutFile $env:USERPROFILE\Desktop\EC2Rescue_latest.zip
   ```

   This command will download the EC2Rescue .zip file to the desktop of the currently logged in user.

   > **Note**
   >
   > If you receive an error when downloading the file, and you are using Windows Server 2016 or earlier, TLS 1.2 might need to be enabled for your PowerShell terminal. You can enable TLS 1.2 for the current PowerShell session with the following command and then try again:
   >
   > ```
   > [Net.ServicePointManager]::SecurityProtocol =
   >  [Net.SecurityProtocolType]::Tls12
   > ```

3. Open the EC2Rescue for Windows Server application and accept the license agreement.
4. Choose **Next**, **Current instance**, **Capture logs**.
5. Select the data items to collect and choose **Collect...**. Read the warning and choose **Yes** to continue.
6. Choose a file name and location for the ZIP file and choose **Save**.
7. After EC2Rescue for Windows Server completes, choose **Open Containing Folder** to view the ZIP file.
8. Choose **Finish**.

Troubleshoot impaired Windows instance with the EC2Rescue CLI

The EC2Rescue for Windows Server command line interface (CLI) allows you to run an EC2Rescue for Windows Server plugin (referred as an "action") programmatically.

The EC2Rescue for Windows Server tool has two execution modes:

- **/online**—This allows you to take action on the instance that EC2Rescue for Windows Server is installed on, such as collect log files.
- **/offline:<device_id>**—This allows you to take action on the offline root volume that is attached to a separate Amazon EC2 Windows instance, on which you have installed EC2Rescue for Windows Server.

Download the tool to your Windows instance and extract the files. You can view the help file using the following command:

```
EC2RescueCmd.exe /help
```

EC2Rescue for Windows Server can perform the following actions on an Amazon EC2 Windows instance:

- Collect action
- Rescue action
- Restore action

Collect action

> **Note**
>
> You can collect all logs, an entire log group, or an individual log within a group.

EC2Rescue for Windows Server can collect the following data from **active and offline instances**.

Log group	Available logs	Description
`all`		Collects all available logs.

Log group	Available logs	Description
`eventlog`	• `'Application'` • `'System'` • `'EC2ConfigService'`	Collects application, system, and EC2Config event logs.
`memory-dump`	• `'Memory Dump File'` • `'Mini Dump Files'`	Collects any memory dump files that exist on the instance.
`ec2config`	• `'Log Files'` • `'Configuration Files'`	Collects log files generated by the EC2Config service.
`ec2launch`	• `'Logs'` • `'Config'`	Collects log files generated by the EC2Launch scripts.
`ssm-agent`	• `'Log Files'` • `'Patch Baseline Logs'` • `'InstanceData'`	Collects log files generated by SSM Agent and Patch Manager logs.
`sysprep`	`'Log Files'`	Collects log files generated by the Windows System Preparation tool.
`driver-setup`	• `'SetupAPI Log Files'` • `'DPInst Log File'` • `'AWS PV Setup Log File'`	Collects Windows SetupAPI logs (`setupapi.dev.log` and `setupapi.setup.log`).
`registry`	• `'SYSTEM'` • `'SOFTWARE'` • `'BCD'`	Collects `SYSTEM` and `SOFTWARE` hives.
`egpu`	• `'Event Log'` • `'System Files'`	Collects event logs related to elastic GPUs.

Log group	Available logs	Description
`boot-config`	`'BCDEDIT Output'`	Collects `HKEY_LOCAL_MACHINE\BCD00000000` hive.
`windows-update`	`'Log Files'`	Collects log files generated by Windows Update. **Note** In Windows Server 2016 and later, the log is collected in Event Tracing for Windows (ETW) format.
`cloudendure`	• `'Migrate Script Logs'` • `'Driver Logs'` • `'CloudEndure File List'`	Collects log files related to CloudEndure Agent.

EC2Rescue for Windows Server can collect the following additional data from **active instances**.

Log group	Available logs	Description
`system-info`	`'MSInfo32 Output'`	Collects `MSInfo32`.
`gpresult`	`'GPResult Output'`	Collects a Group Policy report.

The following are the available options:

- **/output:<outputFilePath>** - Required destination file path location to save collected log files in zip format.

- **/no-offline** - Optional attribute used in offline mode. Does not set the volume offline after completing the action.
- **/no-fix-signature** - Optional attribute used in offline mode. Does not fix a possible disk signature collision after completing the action.

Examples

The following are examples using the EC2Rescue for Windows Server CLI.

Online mode examples

Collect all available logs:

```
EC2RescueCmd /accepteula /online /collect:all /output:<outputFilePath>
```

Collect only a specific log group:

```
EC2RescueCmd /accepteula /online /collect:ec2config /output:<outputFilePath>
```

Collect individual logs within a log group:

```
EC2RescueCmd /accepteula /online /collect:'ec2config.Log Files,driver-setup.SetupAPI
 Log Files' /output:<outputFilePath>
```

Offline mode examples

Collect all available logs from an EBS volume. The volume is specified by the device_id value.

```
EC2RescueCmd /accepteula /offline:xvdf /collect:all /output:<outputFilePath>
```

Collect only a specific log group:

```
EC2RescueCmd /accepteula /offline:xvdf /collect:ec2config /output:<outputFilePath>
```

Rescue action

EC2Rescue for Windows Server can detect and address issues with the following service settings:

Service group	Available actions	Description
`all`		
`system-time`	`'RealTimeIsUniversal'`	System Time • **RealTimeisUniversal** - Detects whether the `RealTimeisUniversal` registry key is enabled. If disabled, Windows system time drifts when the timezone is set to a value other than UTC.
`firewall`	• `'Domain networks'` • `'Private networks'` • `'Guest or public networks'`	Windows Firewall • **Domain networks** - Detects whether this Windows Firewall profile is enabled or disabled. • **Private networks** - Detects whether this Windows Firewall profile is enabled or disabled. • **Guest or public networks** - Detects whether this Windows Firewall profile is enabled or disabled.
rdp	• `'Service Start'` • `'Remote Desktop Connections'` • `'TCP Port'`	Remote Desktop • **Service Start** - Detects whether the Remote Desktop service is enabled.

Service group	Available actions	Description
		• **Remote Desktop Connections** - Detects whether this is enabled. • **TCP Port** - Detects which port the Remote Desktop service is listening on.
`ec2config`	• `'Service Start'` • `'Ec2SetPassword'` • `'Ec2HandleUserData'`	EC2Config • **Service Start** - Detects whether the EC2Config service is enabled. • **Ec2SetPassword** - Generates a new administrator password. • **Ec2HandleUserData** - Allows you to run a user data script on the next boot of the instance.
`ec2launch`	`'Reset Administrator Password'`	Generates a new Windows administrator password.
`network`	`'DHCP Service Startup'`	Network Interface • **DHCP Service Startup** - Detects whether the DHCP service is enabled.

The following are the available options:

- **/level:<level>** - Optional attribute for the check level that the action should trigger. Allowed values are: `information`, `warning`, `error`, `all`. By default, it is set to `error`.
- **/check-only** - Optional attribute that generates a report but makes no modifications to the offline volume.

> **Note**
>
> If EC2Rescue for Windows Server detects a possible disk signature collision, it corrects the signature after the offline process completes by default, even when you use the `/check-only` option. You must use the `/no-fix-signature` option to prevent the correction.

- **/no-offline** - Optional attribute that prevents the volume from being set offline after completing the action.
- **/no-fix-signature** - Optional attribute that does not fix a possible disk signature collision after completing the action.

Rescue examples

The following are examples using the EC2Rescue for Windows Server CLI. The volume is specified using the device_id value.

Attempt to fix all identified issues on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:all
```

Attempt to fix all issues within a service group on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:firewall
```

Attempt to fix a specific item within a service group on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:rdp.'Service Start'
```

Specify multiple issues to attempt to fix on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:'system-
time.RealTimeIsUniversal,ec2config.Service Start'
```

Restore action

EC2Rescue for Windows Server can detect and address issues with the following service settings:

Service Group	Available Actions	Description
Restore Last Known Good Configuration	`lkgc`	**Last Known Good Configuration** - Attempts to boot the instance into the last known bootable state.
Restore Windows registry from latest backup	`regback`	**Restore registry from backup** - Restores the registry from `\Windows\System32\config\RegBack .`

The following are the available options:

- **/no-offline**—Optional attribute that prevents the volume from being set offline after completing the action.
- **/no-fix-signature**—Optional attribute that does not fix a possible disk signature collision after completing the action.

Restore examples

The following are examples using the EC2Rescue for Windows Server CLI. The volume is specified using the device_id value.

Restore last known good configuration on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /restore:lkgc
```

Restore the last Windows registry backup on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /restore:regback
```

Troubleshoot impaired Windows instance with EC2Rescue and Systems Manager

Support provides you with a Systems Manager Run Command document to interface with your Systems Manager-enabled instance to run EC2Rescue for Windows Server. The Run Command document is called `AWSSupport-RunEC2RescueForWindowsTool`.

This Systems Manager Run Command document performs the following tasks:

- Downloads and verifies EC2Rescue for Windows Server.
- Imports a PowerShell module to ease your interaction with the tool.
- Runs EC2RescueCmd with the provided command and parameters.

The Systems Manager Run Command document accepts three parameters:

- **Command**—The EC2Rescue for Windows Server action. The current allowed values are:
  - **ResetAccess**—Resets the local Administrator password. The local Administrator password of the current instance will be reset and the randomly generated password will be securely stored in Parameter Store as `/EC2Rescue/Password/<INSTANCE_ID>`. If you select this action and provide no parameters, passwords are encrypted automatically with the default KMS key. Optionally, you can specify a KMS key ID in Parameters to encrypt the password with your own key.
  - **CollectLogs**—Runs EC2Rescue for Windows Server with the `/collect:all` action. If you select this action, `Parameters` must include an Amazon S3 bucket name to upload the logs to.
  - **FixAll**—Runs EC2Rescue for Windows Server with the `/rescue:all` action. If you select this action, `Parameters` must include the block device name to rescue.
- **Parameters**—The PowerShell parameters to pass for the specified command.

Requirements

To run the **ResetAccess** action, your Amazon EC2 instance must have the a policy attached that grants permissions to write the encrypted password to Parameter Store. After attaching the policy, wait a few minutes before attempting to reset the password of an instance after you have attached this policy to the related IAM role.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:PutParameter"
      ],
      "Resource": [
        "arn:aws-eusc:ssm:eusc-de-east-1:111122223333:parameter/EC2Rescue/
Passwords/<instanceid>"
      ]
    }
  ]
}
```

If you are using a custom KMS key, not the default KMS key, use this policy instead.

  ]
}
```

View the JSON for the document

The following procedure describes how to view the JSON for this document.

To view the JSON for the Systems Manager Run Command document

1. Open the AWS Systems Manager console at https://eusc-de-east-1.console.amazonaws-eusc.eu/systems-manager/.
2. In the navigation pane, expand **Change Management Tools** and choose **Documents**.
3. In the search bar, enter `AWSSupport-RunEC2RescueForWindowsTool`, and then select the `AWSSupport-RunEC2RescueForWindowsTool` document.
4. Choose the **Content** tab.

Examples

Here are some examples on how to use the Systems Manager Run Command document to run EC2Rescue for Windows Server, using the AWS CLI. For more information about sending commands using the AWS CLI, see send-command.

Examples

- Attempt to fix all identified issues on an offline root volume
- Collect logs from the current Amazon EC2 Windows instance
- Reset the local Administrator password

Attempt to fix all identified issues on an offline root volume

Attempt to fix all identified issues on an offline root volume attached to an Amazon EC2 Windows instance:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-
RunEC2RescueForWindowsTool" --parameters "Command=FixAll, Parameters='xvdf'" --output
 text
```

Collect logs from the current Amazon EC2 Windows instance

Collect all logs from the current online Amazon EC2 Windows instance and upload them to an Amazon S3 bucket:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-
RunEC2RescueForWindowsTool" --parameters "Command=CollectLogs, Parameters='amzn-s3-
demo-bucket'" --output text
```

Reset the local Administrator password

The following examples show methods you can use to reset the local Administrator password. The output provides a link to Parameter Store, where you can find the randomly generated secure password you can then use to RDP to your Amazon EC2 Windows instance as the local Administrator.

Reset the local Administrator password of an online instance using the default AWS KMS key alias/aws/ssm:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-
RunEC2RescueForWindowsTool" --parameters "Command=ResetAccess" --output text
```

Reset the local Administrator password of an online instance using a KMS key:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-
RunEC2RescueForWindowsTool" --parameters "Command=ResetAccess, Parameters=a133dc3c-
a2g4-4fc6-a873-6c0720104bf0" --output text
```

> **Note**
>
> In this example, the KMS key is `a133dc3c-a2g4-4fc6-a873-6c0720104bf0`.

EC2 Serial Console for instances

With the EC2 serial console, you have access to your Amazon EC2 instance's serial port, which you can use to troubleshoot boot, network configuration, and other issues. The serial console does not require your instance to have any networking capabilities. With the serial console, you can enter commands to an instance as if your keyboard and monitor are directly attached to the instance's serial port. The serial console session lasts during instance reboot and stop. During reboot, you can view all of the boot messages from the start.

Access to the serial console is not available by default. Your organization must grant account access to the serial console and configure IAM policies to grant your users access to the serial console. Serial console access can be controlled at a granular level by using instance IDs, resource tags, and other IAM levers. For more information, see Configure access to the EC2 Serial Console.

The serial console can be accessed by using the EC2 console or the AWS CLI.

The serial console is available at no additional cost.

Topics

- Prerequisites for the EC2 Serial Console
- Configure access to the EC2 Serial Console
- Connect to the EC2 Serial Console
- Disconnect from the EC2 Serial Console
- Troubleshoot your Amazon EC2 instance using the EC2 Serial Console

Prerequisites for the EC2 Serial Console

To connect to the EC2 Serial Console and use your chosen tool for troubleshooting, the following prerequisites must be met:

- AWS Regions
- Wavelength Zones
- AWS Outposts
- Local Zones
- Instance types

- Grant access
- Support for browser-based client
- Instance state
- Amazon EC2 Systems Manager
- Configure your chosen troubleshooting tool

AWS Regions

Supported in all AWS Regions except AWS European Sovereign Cloud (Germany).

Wavelength Zones

Not supported.

AWS Outposts

Supported on all AWS Outposts.

Local Zones

Supported in all Local Zones.

Instance types

Supported instance types:

- **Linux**
  - All virtualized instances built on the Nitro System.
  - All bare metal instances except:
    - General purpose: `a1.metal`, `mac1.metal`, `mac2.metal`, `mac2-m1ultra.metal`, `mac2-m2.metal`, `mac2-m2pro.metal`, `mac-m3ultra.metal`, `mac-m4.metal`, `mac-m4max.metal`, and `mac-m4pro.metal`
    - Accelerated computing: `g5g.metal`
    - Memory optimized: `u-6tb1.metal`, `u-9tb1.metal`, `u-12tb1.metal`, `u-18tb1.metal`, and `u-24tb1.metal`
- **Windows**

- All virtualized instances built on the Nitro System.
- All bare metal instances except:
  - General purpose: `a1.metal`, `mac1.metal`, `mac2.metal`, `mac2-m1ultra.metal`, `mac2-m2.metal`, `mac2-m2pro.metal`, `mac-m3ultra.metal`, `mac-m4.metal`, `mac-m4max.metal`, and `mac-m4pro.metal`
  - Accelerated computing: `g5g.metal`
  - Memory optimized: `u-6tb1.metal`, `u-9tb1.metal`, `u-12tb1.metal`, `u-18tb1.metal`, and `u-24tb1.metal`

Grant access

You must complete the configuration tasks to grant access to the EC2 Serial Console. For more information, see Configure access to the EC2 Serial Console.

Support for browser-based client

To connect to the serial console using the browser-based client, your browser must support WebSocket. If your browser does not support WebSocket, connect to the serial console using your own key and an SSH client.

The browser-based client connects on port 443 to the EC2 Instance Connect proxy endpoint for your Region. The endpoint format depends on the partition:

- Commercial AWS Regions and AWS GovCloud (US) Regions use the endpoint format: `prod.`*`region`*`.oneclickv2-proxy.ec2.aws.dev`.
- China Regions use the endpoint format: `prod.`*`region`*`.oneclickv2-proxy.ec2.a2z.org.cn`.

The following examples show the endpoint for each partition:

- For the US East (N. Virginia) Region, the endpoint is `prod.us-east-1.oneclickv2-proxy.ec2.aws.dev`.
- For the China (Beijing) Region, the endpoint is `prod.cn-north-1.oneclickv2-proxy.ec2.a2z.org.cn`.

> **Note**
>
> Your browser must be able to reach this endpoint. If a firewall or VPN blocks the connection, the connection fails.

Instance state

Must be `running`.

You can't connect to the serial console if the instance is in the `pending`, `stopping`, `stopped`, `shutting-down`, or `terminated` state.

For more information about the instance states, see Amazon EC2 instance state changes.

Amazon EC2 Systems Manager

If the instance uses Amazon EC2 Systems Manager, then SSM Agent version 3.0.854.0 or later must be installed on the instance. For information about SSM Agent, see Working with SSM Agent in the *AWS Systems Manager User Guide*.

Configure your chosen troubleshooting tool

To troubleshoot your instance using the serial console, you can use GRUB or SysRq on Linux instances, and the Special Admin Console (SAC) on Windows instances. Before you can use these tools, you must first perform configuration steps on every instance on which you'll use them.

Use the following instructions to configure GRUB or SysRq on a Linux instance. For Windows instances, to enable and use SAC, see Troubleshoot your Windows instance using SAC.

(Linux instances) Configure GRUB

To configure GRUB, choose one of the following procedures based on the AMI that was used to launch the instance.

Amazon Linux 2

To configure GRUB on an Amazon Linux 2 instance

1. Connect to your Linux instance using SSH

2. Add or change the following options in `/etc/default/grub`:

   - Set `GRUB_TIMEOUT=1`.
   - Add `GRUB_TERMINAL="console serial"`.
   - Add `GRUB_SERIAL_COMMAND="serial --speed=115200"`.

   The following is an example of `/etc/default/grub`. You might need to change the configuration based on your system setup.

   ```
   GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0
    biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.shell=0"
   GRUB_TIMEOUT=1
   GRUB_DISABLE_RECOVERY="true"
   GRUB_TERMINAL="console serial"
   GRUB_SERIAL_COMMAND="serial --speed=115200"
   ```

3. Apply the updated configuration by running the following command.

   ```
   [ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

Ubuntu

To configure GRUB on an Ubuntu instance

1. Connect to your instance.
2. Add or change the following options in `/etc/default/grub.d/50-cloudimg-settings.cfg`:

   - Set `GRUB_TIMEOUT=1`.
   - Add `GRUB_TIMEOUT_STYLE=menu`.
   - Add `GRUB_TERMINAL="console serial"`.
   - Remove `GRUB_HIDDEN_TIMEOUT`.
   - Add `GRUB_SERIAL_COMMAND="serial --speed=115200"`.

   The following is an example of `/etc/default/grub.d/50-cloudimg-settings.cfg`. You might need to change the configuration based on your system setup.

```
# Cloud Image specific Grub settings for Generic Cloud Images
# CLOUD_IMG: This file was created/modified by the Cloud Image build process

# Set the recordfail timeout
GRUB_RECORDFAIL_TIMEOUT=0

# Do not wait on grub prompt
GRUB_TIMEOUT=1
GRUB_TIMEOUT_STYLE=menu

# Set the default commandline
GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0
 nvme_core.io_timeout=4294967295"

# Set the grub console type
GRUB_TERMINAL="console serial"
GRUB_SERIAL_COMMAND="serial --speed 115200"
```

3. Apply the updated configuration by running the following command.

```
[ec2-user ~]$ sudo update-grub
```

RHEL

To configure GRUB on a RHEL instance

1. Connect to your instance.
2. Add or change the following options in `/etc/default/grub`:
   - Remove `GRUB_TERMINAL_OUTPUT`.
   - Add `GRUB_TERMINAL="console serial"`.
   - Add `GRUB_SERIAL_COMMAND="serial --speed=115200"`.

   The following is an example of `/etc/default/grub`. You might need to change the configuration based on your system setup.

```
GRUB_TIMEOUT=1
GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
```

```
GRUB_DEFAULT=saved
GRUB_DISABLE_SUBMENU=true
GRUB_CMDLINE_LINUX="console=tty0 console=ttyS0,115200n8 net.ifnames=0
 rd.blacklist=nouveau nvme_core.io_timeout=4294967295 crashkernel=auto"
GRUB_DISABLE_RECOVERY="true"
GRUB_ENABLE_BLSCFG=true
GRUB_TERMINAL="console serial"
GRUB_SERIAL_COMMAND="serial --speed=115200"
```

3. Apply the updated configuration by running the following command.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg --update-bls-cmdline
```

For RHEL 9.2 and earlier, use the following command.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

CentOS

For instances that are launched using a CentOS AMI, GRUB is configured for the serial console by default.

The following is an example of `/etc/default/grub`. Your configuration might be different based on your system setup.

```
GRUB_TIMEOUT=1
GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
GRUB_DEFAULT=saved
GRUB_DISABLE_SUBMENU=true
GRUB_TERMINAL="serial console"
GRUB_SERIAL_COMMAND="serial --speed=115200"
GRUB_CMDLINE_LINUX="console=tty0 crashkernel=auto console=ttyS0,115200"
GRUB_DISABLE_RECOVERY="true"
```

(Linux instances) Configure SysRq

To configure SysRq, you enable the SysRq commands for the current boot cycle. To make the configuration persistent, you can also enable the SysRq commands for subsequent boots.

To enable all SysRq commands for the current boot cycle

1. Connect to your instance.
2. Run the following command.

```
[ec2-user ~]$ sudo sysctl -w kernel.sysrq=1
```

   This setting will clear on the next reboot.

To enable all SysRq commands for subsequent boots

1. Create the file `/etc/sysctl.d/99-sysrq.conf` and open it in your favorite editor.

```
[ec2-user ~]$ sudo vi /etc/sysctl.d/99-sysrq.conf
```

2. Add the following line.

```
kernel.sysrq=1
```

3. Reboot the instance to apply the changes.

```
[ec2-user ~]$ sudo reboot
```

4. At the `login` prompt, enter the username of the password-based user that you set up previously, and then press **Enter**.
5. At the `Password` prompt, enter the password, and then press **Enter**.

Configure access to the EC2 Serial Console

To configure access to the serial console, you must grant serial console access at the account level and then configure IAM policies to grant access to your users. For Linux instances you must also configure a password-based user on every instance so that your users can use the serial console for troubleshooting.

EC2 Serial Console uses a virtual serial port connection to interact with an instance. This connection is independent of the instance VPC, so that you can work with the instance operating system and run troubleshooting tools even if there are boot failures or network configuration

issues. Because this connection is outside of the VPC network, EC2 Serial Console does not use the instance security group or the subnet network ACL to authorize traffic to the instance.

Before you begin

Verify that the prerequisites are met.

Contents

- Levels of access to the EC2 Serial Console
- Manage account access to the EC2 Serial Console
- Configure IAM policies for EC2 Serial Console access
- Set an OS user password on a Linux instance

Levels of access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level. For more information, see Manage account access to the EC2 Serial Console.

You can use a service control policy (SCP) to allow access to the serial console within your organization. You can then have granular access control at the user level by using an IAM policy to control access. By using a combination of SCP and IAM policies, you have different levels of access control to the serial console.

Organization level

You can use a service control policy (SCP) to allow access to the serial console for member accounts within your organization. For more information about SCPs, see Service control policies in the *AWS Organizations User Guide*.

Instance level

You can configure the serial console access policies by using IAM PrincipalTag and ResourceTag constructions and by specifying instances by their ID. For more information, see Configure IAM policies for EC2 Serial Console access.

User level

You can configure access at the user level by configuring an IAM policy to allow or deny a specified user the permission to push the SSH public key to the serial console service of a

particular instance. For more information, see Configure IAM policies for EC2 Serial Console access.

OS level

- **Linux**

  You can set a user password at the guest OS level. This provides access to the serial console for some use cases. However, to monitor the logs, you don't need a password-based user. For more information, see Set an OS user password on a Linux instance.

- **Windows**

  Granting serial console permissions is equivalent to granting admin-level privileges on the instance. Further authentication is driven by Windows and you should consult Microsoft documentation for additional details.

  For more information, see the Microsoft docs at Emergency Management Services Tools and Settings.

Manage account access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level.

This setting is configured at the account level, either directly in the account or by using a declarative policy. It must be configured in each AWS Region where you want to grant access to the serial console. Using a declarative policy allows you to apply the setting across multiple Regions simultaneously, as well as across multiple accounts simultaneously. When a declarative policy is in use, you can't modify the setting directly within an account. This topic describes how to configure the setting directly within an account. For information about using declarative policies, see Declarative policies in the *AWS Organizations User Guide.*

Contents

- Grant permission to users to manage account access
- View account access status to the serial console
- Grant account access to the serial console
- Deny account access to the serial console

Grant permission to users to manage account access

To allow your users to manage account access to the EC2 serial console, you need to grant them the required IAM permissions.

The following policy grants permissions to view the account status, and to allow and prevent account access to the EC2 serial console.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:GetSerialConsoleAccessStatus",
                "ec2:EnableSerialConsoleAccess",
                "ec2:DisableSerialConsoleAccess"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information, see Creating IAM policies in the *IAM User Guide*.

View account access status to the serial console

Console

To view account access to the serial console

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Dashboard**.
3. On the **Account attributes** card, under **Settings**, choose **EC2 Serial Console**.
4. On the **EC2 Serial Console** tab, the value of **EC2 Serial Console access** is either **Allowed** or **Prevented**.

AWS CLI

To view account access to the serial console

Use the get-serial-console-access-status command.

```
aws ec2 get-serial-console-access-status
```

The following is example output. A value of `true` indicates that the account is allowed access to the serial console.

```
{
    "SerialConsoleAccessEnabled": true,
    "ManagedBy": "account"
}
```

The `ManagedBy` field indicates the entity that configured the setting. The possible values are `account` (configured directly) or `declarative-policy`. For more information, see Declarative policies in the *AWS Organizations User Guide*.

PowerShell

To view account access to the serial console

Use the Get-EC2SerialConsoleAccessStatus cmdlet.

```
Get-EC2SerialConsoleAccessStatus -Select *
```

The following is example output. A value of `True` indicates that the account is allowed access to the serial console.

```
ManagedBy SerialConsoleAccessEnabled
--------- --------------------------
account   True
```

The `ManagedBy` field indicates the entity that configured the setting. The possible values are `account` (configured directly) or `declarative-policy`. For more information, see Declarative policies in the *AWS Organizations User Guide*.

Grant account access to the serial console

Console

To grant account access to the serial console

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Dashboard**.
3. On the **Account attributes** card, under **Settings**, choose **EC2 Serial Console**.
4. Choose **Manage**.
5. To allow access to the EC2 serial console of all instances in the account, select the **Allow** checkbox.
6. Choose **Update**.

AWS CLI

To grant account access to the serial console

Use the enable-serial-console-access command.

```
aws ec2 enable-serial-console-access
```

The following is example output.

```
{
    "SerialConsoleAccessEnabled": true
}
```

PowerShell

To grant account access to the serial console

Use the Enable-EC2SerialConsoleAccess cmdlet.

```
Enable-EC2SerialConsoleAccess
```

The following is example output.

```
True
```

Deny account access to the serial console

Console

To deny account access to the serial console

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Dashboard**.
3. On the **Account attributes** card, under **Settings**, choose **EC2 Serial Console**.
4. Choose **Manage**.
5. To prevent access to the EC2 serial console of all instances in the account, clear the **Allow** checkbox.
6. Choose **Update**.

AWS CLI

To deny account access to the serial console

Use the disable-serial-console-access command.

```
aws ec2 disable-serial-console-access
```

The following is example output.

```
{
    "SerialConsoleAccessEnabled": false
}
```

PowerShell

To deny account access to the serial console

Use the Disable-EC2SerialConsoleAccess cmdlet.

```
Disable-EC2SerialConsoleAccess
```

The following is example output.

```
False
```

Configure IAM policies for EC2 Serial Console access

By default, your users do not have access to the serial console. Your organization must configure IAM policies to grant your users the required access. For more information, see Creating IAM policies in the *IAM User Guide*.

For serial console access, create a JSON policy document that includes the `ec2-instance-connect:SendSerialConsoleSSHPublicKey` action. This action grants a user permission to push the public key to the serial console service, which starts a serial console session. We recommend restricting access to specific EC2 instances. Otherwise, all users with this permission can connect to the serial console of all EC2 instances.

Example IAM policies

- Explicitly allow access to the serial console
- Explicitly deny access to the serial console
- Use resource tags to control access to the serial console

Explicitly allow access to the serial console

By default, no one has access to the serial console. To grant access to the serial console, you need to configure a policy to explicitly allow access. We recommend configuring a policy that restricts access to specific instances.

The following policy allows access to the serial console of a specific instance, identified by its instance ID.

Note that the `DescribeInstances`, `DescribeInstanceTypes`, and `GetSerialConsoleAccessStatus` actions do not support resource-level permissions, and therefore all resources, indicated by the `*` (asterisk), must be specified for these actions.

JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowDescribeInstances",
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:GetSerialConsoleAccessStatus"
            ],
             "Resource": "*"
        },
        {
            "Sid": "AllowinstanceBasedSerialConsoleAccess",
            "Effect": "Allow",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
            ],
            "Resource": "arn:aws-eusc:ec2:eusc-de-
east-1:111122223333:instance/i-0598c7d356eba48d7"
        }
    ]
}
```

Explicitly deny access to the serial console

The following IAM policy allows access to the serial console of all instances, denoted by the * (asterisk), and explicitly denies access to the serial console of a specific instance, identified by its ID.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowSerialConsoleAccess",
            "Effect": "Allow",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey",
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:GetSerialConsoleAccessStatus"
```

```
            ],
            "Resource": "*"
        },
        {
            "Sid": "DenySerialConsoleAccess",
            "Effect": "Deny",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
            ],
            "Resource": "arn:aws-eusc:ec2:eusc-de-
east-1:111122223333:instance/i-0598c7d356eba48d7"
        }
    ]
}
```

Use resource tags to control access to the serial console

You can use resource tags to control access to the serial console of an instance.

Attribute-based access control is an authorization strategy that defines permissions based on tags that can be attached to users and AWS resources. For example, the following policy allows a user to initiate a serial console connection for an instance only if that instance's resource tag and the principal's tag have the same `SerialConsole` value for the tag key.

For more information about using tags to control access to your AWS resources, see Controlling access to AWS resources in the *IAM User Guide*.

Note that the `DescribeInstances`, `DescribeInstanceTypes`, and `GetSerialConsoleAccessStatus` actions do not support resource-level permissions, and therefore all resources, indicated by the `*` (asterisk), must be specified for these actions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowDescribeInstances",
            "Effect": "Allow",
            "Action": [
```

```
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:GetSerialConsoleAccessStatus"
            ],
            "Resource": "*"
        },
        {
            "Sid": "AllowTagBasedSerialConsoleAccess",
            "Effect": "Allow",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
            ],
            "Resource": "arn:aws-eusc:ec2:eusc-de-east-1:111122223333:instance/
*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/SerialConsole":
 "${aws:PrincipalTag/SerialConsole}"
                }
            }
        }
    ]
}
```

Set an OS user password on a Linux instance

You can connect to the serial console without a password. However, to *use* the serial console for troubleshooting a Linux instance, the instance must have a password-based OS user.

You can set the password for any OS user, including the root user. Note that the root user can modify all files, while each OS user might have limited permissions.

You must set a user password for every instance for which you will use the serial console. This is a one-time requirement for each instance.

> **Note**
>
> By default, AMIs provided by AWS are not configured with a password-based user. If you launched your instance using an AMI that already has the root user password configured, you can skip these instructions.

To set an OS user password on a Linux instance

1. Connect to your instance. You can use any method for connecting to your instance, except the EC2 Serial Console connection method.
2. To set the password for a user, use the **passwd** command. In the following example, the user is `root`.

   ```
   [ec2-user ~]$ sudo passwd root
   ```

   The following is example output.

   ```
   Changing password for user root.
   New password:
   ```

3. At the `New password` prompt, enter the new password.
4. At the prompt, re-enter the password.

Connect to the EC2 Serial Console

You can connect to the serial console of your EC2 instance by using the Amazon EC2 console or through SSH. After connecting to the serial console, you can use it for troubleshooting boot, network configuration, and other issues. For more information about troubleshooting, see Troubleshoot your Amazon EC2 instance using the EC2 Serial Console.

Considerations

- Only 1 active serial console connection is supported per instance.
- The serial console connection typically lasts for 1 hour unless you disconnect from it. However, during system maintenance, Amazon EC2 will disconnect the serial console session.

  The duration of the connection is not determined by the duration of your IAM credentials. If your IAM credentials expire, the connection continues to persist until the maximum duration of the serial console connection is reached. When using the EC2 Serial Console console experience, if your IAM credentials expire, terminate the connection by closing the browser page.
- It takes 30 seconds to tear down a session after you've disconnected from the serial console to allow a new session.
- Supported serial console ports: `ttyS0` (Linux instances) and `COM1` (Windows instances)

- When you connect to the serial console, you might observe a slight drop in your instance's throughput.

Topics

- Connect using the browser-based client
- Connect using your own key and SSH client
- EC2 Serial Console endpoints and fingerprints

Connect using the browser-based client

You can connect to your EC2 instance's serial console by using the browser-based client. You do this by selecting the instance in the Amazon EC2 console and choosing to connect to the serial console. The browser-based client handles the permissions and provides a successful connection.

EC2 serial console works from most browsers, and supports keyboard and mouse input.

Before connecting, make sure you have completed the prerequisites.

To connect to your instance's serial port using the browser-based client (Amazon EC2 console)

1. Open the Amazon EC2 console at https://eusc-de-east-1.console.amazonaws-eusc.eu/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **EC2 Serial Console**, **Connect**.

   Alternatively, select the instance and choose **Connect**, **EC2 Serial Console**, **Connect**.

   An in-browser terminal window opens.
4. Press **Enter**. If a login prompt returns, you are connected to the serial console.

   If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

   - **Check that you have configured access to the serial console.** For more information, see Configure access to the EC2 Serial Console.
   - (Linux instances only) **Use SysRq to connect to the serial console.** SysRq does not require that you connect using the browser-based client. For more information, see (Linux instances) Use SysRq to troubleshoot your instance.

- (Linux instances only) **Restart getty.** If you have SSH access to your instance, then connect to your instance using SSH, and restart getty using the following command.

  ```
  [ec2-user ~]$ sudo systemctl restart serial-getty@ttyS0
  ```

- **Reboot your instance.** You can reboot your instance by using SysRq (Linux instances), the EC2 console, or the AWS CLI. For more information, see (Linux instances) Use SysRq to troubleshoot your instance (Linux instances) or Reboot your Amazon EC2 instance.

5. (Linux instances only) At the `login` prompt, enter the username of the password-based user that you set up previously, and then press **Enter**.
6. (Linux instances only) At the `Password` prompt, enter the password, and then press **Enter**.

Connect using your own key and SSH client

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the serial console API. This enables you to benefit from the serial console capability to push a public key to the instance.

After pushing the SSH key to the instance, the SSH connection is not subject to the IAM policies that you configured to grant users EC2 Serial Console access.

Before you begin

Verify that the prerequisites are met.

To connect to an instance's serial console using SSH

1. **Push your SSH public key to the instance to start a serial console session**

   Use the send-serial-console-ssh-public-key command to push your SSH public key to the instance. This starts a serial console session.

   If a serial console session has already been started for this instance, the command fails because you can only have one session open at a time. It takes 30 seconds to tear down a session after you've disconnected from the serial console to allow a new session.

   ```
   aws ec2-instance-connect send-serial-console-ssh-public-key \
       --instance-id i-001234a4bf70dec41EXAMPLE \
       --serial-port 0 \
       --ssh-public-key file://my_key.pub \
   ```

```
    --region us-east-1
```

2. **Connect to the serial console using your private key**

   Use the **ssh** command to connect to the serial console before the public key is removed from the serial console service. You have 60 seconds before it is removed.

   Use the private key that corresponds to the public key.

   The username format is `instance-id.port0`, which comprises the instance ID and port 0. In the following example, the username is `i-001234a4bf70dec41EXAMPLE.port0`.

   The endpoint of the serial console service is different for each Region. See the EC2 Serial Console endpoints and fingerprints table for each Region's endpoint. In the following example, the serial console service is in the us-east-1 Region.

   ```
   ssh -i my_key i-001234a4bf70dec41EXAMPLE.port0@serial-console.ec2-instance-connect.us-east-1.aws
   ```

   The following example uses `timeout 3600` to set your SSH session to terminate after 1 hour. Processes started during the session may continue running on your instance after the session terminates.

   ```
   timeout 3600 ssh -i my_key i-001234a4bf70dec41EXAMPLE.port0@serial-console.ec2-instance-connect.us-east-1.aws
   ```

3. **(Optional) Verify the fingerprint**

   When you connect for the first time to the serial console, you are prompted to verify the fingerprint. You can compare the serial console fingerprint with the fingerprint that's displayed for verification. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, you can confidently connect to the serial console.

   The following fingerprint is for the serial console service in the us-east-1 Region. For the fingerprints for each Region, see EC2 Serial Console endpoints and fingerprints.

   ```
   SHA256:dXwn5ma/xadVMeBZGEru5l2gx+yI5LDiJaLUcz0FMmw
   ```

   The fingerprint only appears the first time you connect to the serial console.

4. Press **Enter**. If a prompt returns, you are connected to the serial console.

If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

- **Check that you have configured access to the serial console.** For more information, see Configure access to the EC2 Serial Console.
- (Linux instances only) **Use SysRq to connect to the serial console.** SysRq does not require that you connect using SSH. For more information, see (Linux instances) Use SysRq to troubleshoot your instance.
- (Linux instances only) **Restart getty.** If you have SSH access to your instance, then connect to your instance using SSH, and restart getty using the following command.

```
[ec2-user ~]$ sudo systemctl restart serial-getty@ttyS0
```

- **Reboot your instance.** You can reboot your instance by using SysRq (Linux instances only), the EC2 console, or the AWS CLI. For more information, see (Linux instances) Use SysRq to troubleshoot your instance (Linux instances only) or Reboot your Amazon EC2 instance.

5. (Linux instances only) At the `login` prompt, enter the username of the password-based user that you set up previously, and then press **Enter**.
6. (Linux instances only) At the `Password` prompt, enter the password, and then press **Enter**.

EC2 Serial Console endpoints and fingerprints

The following are the service endpoints and fingerprints for EC2 Serial Console. To connect programmatically to an instance's serial console, you use an EC2 Serial Console endpoint. The EC2 Serial Console endpoints and fingerprints are unique for each AWS Region.

Region Name	Region	Endpoint	Fingerprint
US East (Ohio)	us-east-2	serial-console.ec2-instance-connect.us-east-2.aws	SHA256:EhwPkTzRtTY7TRSzz26XbB0/HvV9jRM7mCZN0xw/d/0

Region Name	Region	Endpoint	Fingerprint
US East (N. Virginia)	us-east-1	serial-console.ec2-instance-connect.us-east-1.aws	SHA256:dXwn5ma/xadVMeBZGEru5l2gx+yI5LDiJaLUcz0FMmw
US West (N. California)	us-west-1	serial-console.ec2-instance-connect.us-west-1.aws	SHA256:OHldlcMET8u7QLSX3jmRTRAPFHVtqbyoLZBMUCqiH3Y
US West (Oregon)	us-west-2	serial-console.ec2-instance-connect.us-west-2.aws	SHA256:EMCIe23TqKaBI6yGHainqZcMwqNkDhhAVHa1O2JxVUc
Africa (Cape Town)	af-south-1	ec2-serial-console.af-south-1.api.aws	SHA256:RMWWZ2fVePeJUqzjO5jL2KIgXsczoHlz21Ed00biiWI
Asia Pacific (Hong Kong)	ap-east-1	ec2-serial-console.ap-east-1.api.aws	SHA256:T0Q1lpiXxChoZHplnAkjbP7tkm2xXViC9bJFsjYnifk
Asia Pacific (Taipei)	ap-east-2	ec2-serial-console.ap-east-2.api.aws	SHA256:z1rsF5DE8aQqsHwBr/D40tR2GnyMqnScCUa1z1eFwDQ

Disconnect from the EC2 Serial Console

If you no longer need to be connected to your instance's EC2 Serial Console, you can disconnect from it. When you disconnect from the serial console, any shell session running on the instance will continue to run. If you want to end the shell session, you'll need to end it before disconnecting from the serial console.

Considerations

- The serial console connection typically lasts for 1 hour unless you disconnect from it. However, during system maintenance, Amazon EC2 will disconnect the serial console session.
- It takes 30 seconds to tear down a session after you've disconnected from the serial console to allow a new session.

The way to disconnect from the serial console depends on the client.

Browser-based client

To disconnect from the serial console, close the serial console in-browser terminal window.

Standard OpenSSH client

To disconnect from the serial console, use the following command to close the SSH connection. This command must be run immediately following a new line.

```
~.
```

The command that you use for closing an SSH connection might be different depending on the SSH client that you're using.

Troubleshoot your Amazon EC2 instance using the EC2 Serial Console

By using EC2 Serial Console, you can troubleshoot boot, network configuration, and other issues by connecting to your instance's serial port.

Use the instructions for your instance's operating system and for the tool you've configured on your instance.

Tools

- (Linux instances) Use GRUB to troubleshoot your instance
- (Linux instances) Use SysRq to troubleshoot your instance
- (Windows instances) Use SAC to troubleshoot your instance

Prerequisites

Before you begin, make sure you have completed the prerequisites, including configuring your chosen troubleshooting tool.

(Linux instances) Use GRUB to troubleshoot your instance

GNU GRUB (short for GNU GRand Unified Bootloader, commonly referred to as GRUB) is the default boot loader for most Linux operating systems. From the GRUB menu, you can select which kernel to boot into, or modify menu entries to change how the kernel will boot. This can be useful when troubleshooting a failing instance.

The GRUB menu is displayed during the boot process. The menu is not accessible through normal SSH, but you can access it using the EC2 Serial Console.

You can boot into single user mode or emergency mode. Single user mode will boot the kernel at a lower runlevel. For example, it might mount the filesystem but not activate the network, giving you the opportunity to perform the maintenance necessary to fix the instance. Emergency mode is similar to single user mode except that the kernel runs at the lowest runlevel possible.

To boot into single user mode

1. Connect to the instance's serial console.
2. Reboot the instance using the following command.

   ```
   [ec2-user ~]$ sudo reboot
   ```
3. During reboot, when the GRUB menu appears, press any key to stop the boot process.
4. In the GRUB menu, use the arrow keys to select the kernel to boot into, and press e on your keyboard.
5. Use the arrow keys to locate your cursor on the line containing the kernel. The line begins with either `linux` or `linux16` depending on the AMI that was used to launch the instance. For Ubuntu, two lines begin with `linux`, which must both be modified in the next step.
6. At the end of the line, add the word `single`.

   The following is an example for Amazon Linux 2.

   ```
   linux /boot/vmlinuz-4.14.193-149.317.amzn2.aarch64 root=UUID=d33f9c9a-\
   dadd-4499-938d-ebbf42c3e499 ro  console=tty0 console=ttyS0,115200n8 net.ifname\
   s=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.she\
   ll=0 single
   ```

7. Press **Ctrl+X** to boot into single user mode.
8. At the `login` prompt, enter the username of the password-based user that you set up previously, and then press **Enter**.
9. At the `Password` prompt, enter the password, and then press **Enter**.

To boot into emergency mode

Follow the same steps as single user mode, but at step 6, add the word `emergency` instead of `single`.

(Linux instances) Use SysRq to troubleshoot your instance

The System Request (SysRq) key, which is sometimes referred to as "magic SysRq", can be used to directly send the kernel a command, outside of a shell, and the kernel will respond, regardless of what the kernel is doing. For example, if the instance has stopped responding, you can use the SysRq key to tell the kernel to crash or reboot. For more information, see Magic SysRq key in Wikipedia.

You can use SysRq commands in the EC2 Serial Console browser-based client or in an SSH client. The command to send a break request is different for each client.

To use SysRq, choose one of the following procedures based on the client that you are using.

Browser-based client

To use SysRq in the serial console browser-based client

1. Connect to the instance's serial console.
2. To send a break request, press `CTRL+0` (zero). If your keyboard supports it, you can also send a break request using the Pause or Break key.

   ```
   [ec2-user ~]$ CTRL+0
   ```

3. To issue a SysRq command, press the key on your keyboard that corresponds to the required command. For example, to display a list of SysRq commands, press `h`.

   ```
   [ec2-user ~]$ h
   ```

The h command outputs something similar to the following.

```
[ 1169.389495] sysrq: HELP : loglevel(0-9) reboot(b) crash(c) terminate-all-
tasks(e) memory-full-oom-kill(f) kill-all-tasks(i) thaw-filesystems
(j) sak(k) show-backtrace-all-active-cpus(l) show-memory-usage(m) nice-all-RT-
tasks(n) poweroff(o) show-registers(p) show-all-timers(q) unraw(r
) sync(s) show-task-states(t) unmount(u) show-blocked-tasks(w) dump-ftrace-
buffer(z)
```

SSH client

To use SysRq in an SSH client

1. Connect to the instance's serial console.
2. To send a break request, press ~B (tilde, followed by uppercase B).

```
[ec2-user ~]$ ~B
```

3. To issue a SysRq command, press the key on your keyboard that corresponds to the required command. For example, to display a list of SysRq commands, press h.

```
[ec2-user ~]$ h
```

The h command outputs something similar to the following.

```
[ 1169.389495] sysrq: HELP : loglevel(0-9) reboot(b) crash(c) terminate-all-
tasks(e) memory-full-oom-kill(f) kill-all-tasks(i) thaw-filesystems
(j) sak(k) show-backtrace-all-active-cpus(l) show-memory-usage(m) nice-all-RT-
tasks(n) poweroff(o) show-registers(p) show-all-timers(q) unraw(r
) sync(s) show-task-states(t) unmount(u) show-blocked-tasks(w) dump-ftrace-
buffer(z)
```

Note

The command that you use for sending a break request might be different depending on the SSH client that you're using.

(Windows instances) Use SAC to troubleshoot your instance

The Special Administration Console (SAC) capability of Windows provides a way to troubleshoot a Windows instance. By connecting to the instance's serial console and using SAC, you can interrupt the boot process and boot Windows in safe mode. For information about enabling, using, and disabling SAC and the boot menu, see Troubleshoot your Windows instance using SAC.

Send a diagnostic interrupt to debug an unreachable Amazon EC2 instance

> **Warning**
>
> Diagnostic interrupts are intended for use by advanced users. Incorrect usage could negatively impact your instance. Sending a diagnostic interrupt to an instance could trigger an instance to crash and reboot, which could lead to the loss of data.

You can send a diagnostic interrupt to an unreachable or unresponsive instance to manually trigger a *kernel panic* for a Linux instance, or a *stop error* (commonly referred to as a *blue screen error*) for a Windows instance.

Linux instances

Linux operating systems typically crash and reboot when a kernel panic occurs. The specific behavior of the operating system depends on its configuration. A kernel panic can also be used to cause the instance's operating system kernel to perform tasks, such as generating a crash dump file. You can then use the information in the crash dump file to conduct root cause analysis and debug the instance. The crash dump data is generated locally by the operating system on the instance itself.

Windows instances

In general, Windows operating systems crash and reboot when a stop error occurs, but the specific behavior depends on its configuration. A stop error can also cause the operating system to write debugging information, such as a kernel memory dump, to a file. You can then use this information to conduct root cause analysis to debug the instance. The memory dump data is generated locally by the operating system on the instance itself.

Before sending a diagnostic interrupt to your instance, we recommend that you consult the documentation for your operating system and then make the necessary configuration changes.

Contents

- Supported instance types
- Prerequisites
- Send a diagnostic interrupt

Supported instance types

Diagnostic interrupt is supported on all Nitro-based instance types, except those powered by AWS Graviton processors. For more information, see instances built on the AWS Nitro System and AWS Graviton.

Prerequisites

Before using a diagnostic interrupt, you must configure your instance's operating system. This ensures that it performs the actions that you need when a kernel panic (Linux instances) or stop error (Windows instances) occurs.

Linux instances

To configure Amazon Linux 2 or Amazon Linux 2023 to generate a crash dump when a kernel panic occurs

1. Connect to your instance.
2. Install **kexec** and **kdump**.

   ```
   [ec2-user ~]$ sudo yum install kexec-tools -y
   ```

3. Configure the kernel to reserve an appropriate amount of memory for the secondary kernel. The amount of memory to reserve depends on the total available memory of your instance. Open the `/etc/default/grub` file using your preferred text editor, locate the line that starts with `GRUB_CMDLINE_LINUX_DEFAULT`, and then add the `crashkernel` parameter in the following format: `crashkernel=`*`memory_to_reserve`*. For example, to reserve 256MB, modify the `grub` file as follows:

```
GRUB_CMDLINE_LINUX_DEFAULT="crashkernel=256M console=tty0 console=ttyS0,115200n8
 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff
 rd.shell=0"
GRUB_TIMEOUT=0
GRUB_DISABLE_RECOVERY="true"
```

4. Save the changes and close the `grub` file.
5. Rebuild the GRUB2 configuration file.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

6. On instances based on Intel and AMD processors, the `send-diagnostic-interrupt` command sends an *unknown non-maskable interrupt* (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI. Open the `/etc/sysctl.conf` file using your preferred text editor and add the following.

```
kernel.unknown_nmi_panic=1
```

7. Reboot and reconnect to your instance.
8. Verify that the kernel has been booted with the correct `crashkernel` parameter.

```
$ grep crashkernel /proc/cmdline
```

   The following example output indicates successful configuration.

```
BOOT_IMAGE=/boot/vmlinuz-4.14.128-112.105.amzn2.x86_64 root=UUID=a1e1011e-
e38f-408e-878b-fed395b47ad6 ro crashkernel=256M console=tty0 console=ttyS0,115200n8
 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff
 rd.shell=0
```

9. Verify that the **kdump** service is running.

```
[ec2-user ~]$ systemctl status kdump.service
```

   The following example output shows the result if the **kdump** service is running.

```
kdump.service - Crash recovery kernel arming
   Loaded: loaded (/usr/lib/systemd/system/kdump.service; enabled; vendor preset:
 enabled)
```

```
   Active: active (exited) since Fri 2019-05-24 23:29:13 UTC; 22s ago
  Process: 2503 ExecStart=/usr/bin/kdumpctl start (code=exited, status=0/SUCCESS)
 Main PID: 2503 (code=exited, status=0/SUCCESS)
```

Note

By default, the crash dump file is saved to `/var/crash/`. To change the location, modify the `/etc/kdump.conf` file using your preferred text editor.

To configure SUSE Linux Enterprise, Ubuntu, or Red Hat Enterprise Linux

On instances based on Intel and AMD processors, the `send-diagnostic-interrupt` command sends an *unknown non-maskable interrupt* (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI by adjusting the configuration file for your operating system. For information about how to configure the kernel to crash, see the documentation for your operating system:

- SUSE Linux Enterprise
- Ubuntu
- Red Hat Enterprise Linux (RHEL)

Windows instances

To configure Windows to generate a memory dump when a stop error occurs

1. Connect to your instance.
2. Open the **Control Panel** and choose **System**, **Advanced system settings**.
3. In the **System Properties** dialog box, choose the **Advanced** tab.
4. In the **Startup and Recovery** section, choose **Settings...**.
5. In the **System failure** section, configure the settings as needed, and then choose **OK**.

For more information about configuring Windows stop errors, see Overview of memory dump file options for Windows.

Send a diagnostic interrupt

After you have completed the necessary configuration changes, you can send a diagnostic interrupt to your instance using the AWS CLI or Amazon EC2 API.

AWS CLI

To send a diagnostic interrupt to your instance

Use the send-diagnostic-interrupt command.

```
aws ec2 send-diagnostic-interrupt --instance-id i-1234567890abcdef0
```

PowerShell

To send a diagnostic interrupt to your instance

Use the Send-EC2DiagnosticInterrupt cmdlet.

```
Send-EC2DiagnosticInterrupt -InstanceId i-1234567890abcdef0
```

Document history for the Amazon EC2 User Guide

The following table describes important additions to the Amazon EC2 User Guide starting in 2019. The guide is also updated frequently to address the feedback that you send us.

Change	Description	Date
Permissions checks for EC2 Fast Launch	Added guidance on how Amazon EC2 validates your permissions when you enable EC2 Fast Launch with a launch template, including a security consideration for using the `$Latest` or `$Default` launch template version.	August 14, 2026
Map view for Regions and Zones	The Regions and Zones page in AWS Global View now includes a Map view that displays all your Regions and Zones on an interactive world map. You can toggle between List view and Map view. Your view preference persists across sessions.	August 12, 2026
Replace current root volume with an existing EBS volume	You can replace the current root volume of an Amazon EC2 instance with an existing Amazon EBS volume that you have already configured.	July 9, 2026
Additional launch template overrides for 'instant' EC2 Fleet	EC2 Fleets of type `instant` now support the following additional launch template override parameters: `IamInstanceProfile` ,	July 9, 2026

	`KeyName`, and `Metadata0ptions` .	
Find the SSM parameter for a public AMI	You can find the AWS Systems Manager parameter associated with a public AMI and use it to automatically reference the latest version of that AMI.	July 7, 2026
SEV-SNP on Dedicated Hosts	AMD SEV-SNP is now supported on Dedicated Hosts, enabling you to run your confidential computing workloads on physical servers fully dedicated to your use.	July 1, 2026
AWS Global View	EC2 Global View is now renamed AWS Global View. You can use it to view your EC2 resources and other supported AWS resources across all Regions in a single view.	June 30, 2026
Precision-time placement group	You can use a precision-time placement group to place instances on hardware with direct access to high-precision time sources in the AWS infrastructure.	June 29, 2026

Use watermarks with Allowed AMIs	You can now use AMI watermarks with Allowed AMIs to restrict instance launches to only AMIs with specified watermark filters. The new Allowed AMIs parameter is `ImageWatermarks` with the following filters: `MaximumDaysSinceSourceImageCreated`, `MaximumDaysSinceWatermarkCreated`, `SourceImageRegion`, and `WatermarkKey`.	June 22, 2026
AWS VMClock device for Windows	AWS provides a null (no-function) driver package for Windows that allows the operating system to recognize the device.	June 17, 2026
AMI watermarks	You can use AMI watermarks to track provenance and enforce governance policies for your private AMIs. Watermarks persist when you create AMIs from instances, copy AMIs, or share AMIs with other accounts.	June 10, 2026
Cancel a Capacity Reservation	You can cancel a future-dated Capacity Reservation. Depending on when you cancel, a charge may apply.	June 2, 2026

ENA Express cross-AZ support	ENA Express now supports traffic between Amazon EC2 instances in different Availability Zones within the same Region.	May 11, 2026
Managed resource visibility	You can control whether resources that AWS services provision on your behalf appear in your Amazon EC2 console views and API list operations.	April 22, 2026
Get started with EFA and NIXL	You can use Elastic Fabric Adapter (EFA) with NIXL for disaggregated inference workloads.	March 17, 2026
Tutorial: Launch an EC2 Fleet with Interruptible Capacity Reservations	A new tutorial shows how to create an EC2 Fleet that uses Interruptible Capacity Reservations to make unused reserved capacity available for your interruptible workloads.	March 16, 2026
Capacity Blocks in Local Zones	Capacity Blocks for ML are now available in Local Zones.	February 25, 2026
IMDSv2 enforcement	You can enforce the use of IMDSv2 at the account level for each AWS Region. When enforced, instances can only launch if they're configured to require IMDSv2.	February 24, 2026

Nested virtualization	You can run hypervisors, such as Hyper-V and KVM, inside virtualized Amazon EC2 instances.	February 16, 2026
Secondary Networks	Secondary Networks are virtual networks purpose-built for specialized networking use cases. You can launch select EC2 instances into both a VPC and a Secondary Network.	February 9, 2026
Capacity Blocks sharing	You can share EC2 Capacity Blocks with other AWS accounts in your AWS organization.	February 2, 2026
Instance topology for P6-B300 instances	You can get the instance topology information for `p6-b300.48xlarge` instances.	November 18, 2025
AMI ancestry	You can now trace the origin of an AMI by getting a list of all its ancestor AMIs.	November 12, 2025
Capacity Reservation Topology	You can use the DescribeCapacityReservationTopology API to describe where your reserved capacity will be located relative to each other in the network hierarchy before you launch instances.	October 28, 2025

Optimize CPUs for license savings	You can now configure active CPUs to save on licensing costs for license-included Windows and SQL Server instances.	October 15, 2025
AWSEC2CapacityManagerServiceRolePolicy – new managed policy	Amazon EC2 added the AWSEC2CapacityManagerServiceRolePolicy managed policy to allow you to manage capacity resources and integrate with AWS Organizations on your behalf.	October 15, 2025
GPUPowerUtilization metric	New `GPUPowerUtilization` metric for accelerated computing instances.	October 13, 2025
EC2 Instance Connect Endpoint IPv6 support	EC2 Instance Connect Endpoint now supports IPv6 connectivity. You can now configure EC2 Instance Connect Endpoints to support dual-stack or IPv6 only to connect to instances with IPv6 addresses.	October 2, 2025
Allowed AMIs - new parameters	Allowed AMIs, a feature that enables you to limit the discovery and use of AMIs within your AWS account, now supports four new parameters: AWS Marketplace product codes, AMI names, maximum period since AMI deprecation, and maximum age for AMIs.	September 25, 2025

Detailed performance statistics for instance store volumes	Amazon EC2 provides real-time, high-resolution performance statistics for NVMe instance store volumes attached to Nitro-based instances.	September 16, 2025
Amazon EC2 Mac Dedicated Host updates	Amazon EC2 Mac Dedicated Hosts support Dedicated Host auto recovery and reboot-based host maintenance.	August 28, 2025
AMI copies for Local Zones	You can now copy Amazon EBS-backed AMIs to and from Local Zones.	August 28, 2025
AmazonEC2ImageReferencesAccessPolicy – new managed policy	Amazon EC2 added the AmazonEC2ImageReferencesAccessPolicy managed policy to provide permission to scan all resources types supported by the EC2 DescribeImageReferences API.	August 26, 2025

AMI usage reports	If you share your Amazon Machine Images (AMIs) with other AWS accounts—whether with specific AWS accounts, organizations, organizational units (OUs), or publicly—you can see how these AMIs are used by creating AMI usage reports. The reports provide visibility into which AWS accounts are using your AMIs in EC2 instances or launch templates, and how many instances or launch templates are referencing each AMI.	August 26, 2025
AMI references	You can identify your AWS resources that reference specified Amazon Machine Images (AMIs), regardless of whether the AMIs are public or private, or who owns them. This visibility helps you ensure your resources use the latest compliant AMIs.	August 26, 2025
Modify EC2 Instance Connect Endpoint	You can now modify an existing EC2 Instance Connect Endpoint using the AWS CLI or an SDK.	August 14, 2025
Capacity Reservation sharing enhancements	You can now share Capacity Reservations that you create in cluster placement groups.	August 12, 2025

Updated managed policy for EC2 Instance Connect Endpoint	To support the modification of existing EC2 Instance Connect Endpoints, Amazon EC2 updated the `Ec2InstanceConnectEndpoint` policy to add permissions to assign and unassign IPv6 addresses and modify security groups on network interfaces created by EC2 Instance Connect Endpoint. Amazon EC2 also updated this policy to replace the `Null` condition operator with the `StringLike` condition operator.	July 31, 2025
Instance topology - additional Region support	The DescribeInstanceTopology API is now available in Asia Pacific (Melbourne).	July 31, 2025
Force terminate	You can now force terminate your instance.	July 31, 2025
Instance topology - additional Region support	The DescribeInstanceTopology API is now available in AWS GovCloud (US-West).	July 24, 2025
Skip OS shutdown during instance termination	You can skip the graceful operating system (OS) shutdown when terminating an instance.	July 23, 2025
Skip OS shutdown during instance stop	You can skip the graceful operating system (OS) shutdown when stopping an instance.	July 23, 2025

P6-B200 Capacity Blocks in us-east-1	P6-B200 Capacity Blocks are now available in US East (N. Virginia) - `us-east-1` .	July 23, 2025
Updated managed policy for the EC2 Fast Launch service linked role	To help prevent orphaned resources, Amazon EC2 updated this policy to add permission to describe volumes, volume attributes and network interfaces, and to delete volumes and net work interfaces that EC2 Fast Launch created.	July 17, 2025
EC2 Serial Console - additional Region support	EC2 Serial Console is now also available in Asia Pacific (Thailand) and Mexico (Central).	July 15, 2025
EC2 Instance Connect - additional Region support	EC2 Instance Connect is now also available in Asia Pacific (Thailand) and Mexico (Central).	July 15, 2025
Hardware packet timestamping	You can enable hardware packet timestamping on your EC2 instance to add a 64-bit nanosecond-precision timestamp to every incoming network packet.	June 23, 2025
Delete snapshots during AMI deregistration	When deregistering an AMI, you can automatically delete its associated snapshots at the same time.	May 28, 2025

User-initiated reboot migration	When your instance receives an EC2 scheduled reboot event notification, it is enabled by default for instance migration when you reboot the instance before the event.	May 20, 2025
SIP configuration for Amazon EC2 Mac instances	You can configure System Integrity Protection (SIP) settings for x86 Mac instances and Apple silicon Mac instances.	May 20, 2025
Root volume ownership delegation	You can now automate root volume ownership delegatio n for the Amazon EBS root volume when updating the operating system on Apple silicon Mac instances.	May 20, 2025
Instance topology for P6-B200 instances	You can get the instance topology information for `p6-b200.48xlarge` instances.	May 15, 2025

Updated managed policies for the EC2 Fast Launch service linked role	Updated the EC2 Fast Launch service linked role policy with access to create and maintain Amazon EventBridge event rules, and other actions to enhance the EC2 Fast Launch experience. For more information about permissions granted by the service linked role, see Permissions granted by `EC2FastLaunchServiceRolePolicy`.	May 14, 2025
Updated managed policies for the EC2 Fast Launch full access policy	Updated the EC2 Fast Launch full access policy with permission to Create and Modify Launch Template operations, to create network and security group resources, authorize ingress rules, and delete resources that EC2 Fast Launch created. The policy can additionally describe and create CloudFormation stacks, and delete stacks that EC2 Fast Launch created.	May 14, 2025
Simplified onboarding for EC2 Fast Launch	Updated EC2 Fast Launch to simplify the onboarding process.	May 14, 2025

AWS Config integration with Allowed AMIs	Use the ec2-instance-launched-with-allowed-ami AWS Config rule to check if running or stopped instances were launched with AMIs that meet your Allowed AMIs criteria.	March 11, 2025
Updated AWSEC2CapacityReservationFleetRolePolicy managed policy	Amazon EC2 updated the `AWSEC2CapacityReservationFleetRolePolicy` managed policy to use the `ArnLike` condition operator instead of the `StringLike` condition operator.	March 3, 2025
Time-based AMI copies	You can now request a completion duration for EBS-backed AMI copy operations to ensure that AMI copies are completed within a specific timeframe.	February 25, 2025
Updated AmazonEC2ReadOnlyAccess policy	Amazon EC2 added the `GetSecurityGroupsForVpc` operation to the existing AmazonEC2ReadOnlyAccess policy.	December 27, 2024
Managed instances	You can now view Amazon EC2 managed instances in the EC2 console.	December 1, 2024

Declarative policies	You can now use declarative policies to apply account-level settings across multiple Regions and accounts simultaneously. Declarative policies are supported for configuring EC2 serial console access, Allowed AMIs, IMDS defaults, and block public access settings for VPCs, AMIs, and snapshots. For more information, see Declarative policies in the *AWS Organizations User Guide*, as well as the specific documentation for each supported feature.	December 1, 2024
Allowed AMIs	You can now control the discovery and use of AMIs in Amazon EC2 by specifying criteria that AMIs must meet.	December 1, 2024
Instant Capacity Blocks	You can now reserve Capacity Blocks for ML, that can start as soon as 30 minutes.	November 21, 2024
Future-dated Capacity Reservations	You can now request Capacity Reservations for a future date.	November 21, 2024
Extend Capacity Block	You can now extend the duration of existing Capacity Blocks.	November 21, 2024
6 month Capacity Blocks	You can now reserve Capacity Blocks for ML for up to 6 months (182 days).	November 21, 2024

Saved filter sets	You can now create customized groups of filters and reuse them to efficiently view your EC2 resources.	November 20, 2024
Performance protection	When using attribute-based instance type selection for your EC2 Fleet or Spot Fleet, you can now enable performance protection to ensure that the selected instance types are similar to or exceed a specified performance baseline.	November 20, 2024
Capacity Reservations only	You can now specify that instances will only run in a Capacity Reservation or Capacity Reservation resource group.	November 20, 2024
Identify source AMI	You can now identify the source AMI that was used to create an AMI.	November 13, 2024
Split capacity	You can split off capacity from an existing Capacity Reservation to create a new reservation.	October 30, 2024
Move capacity	You can now move capacity from one Capacity Reservation to another.	October 30, 2024

Beginner tutorials	Two new tutorials for beginners: Launch my very first EC2 instance and Launch a test EC2 instance and connect to it.	October 21, 2024
Windows Server 2025 support	Add support for Windows Server 2025.	October 16, 2024
EC2 Global View	EC2 Global View now enables you to view Capacity Reservations and Capacity Blocks in your account across all Regions.	October 16, 2024
Live migration host maintenance	Amazon EC2 Dedicated Hosts now support live migration host maintenance, which automatically migrates sup ported instances from an impaired Dedicated Host to a replacement Dedicated Host without stopping and res tarting them.	October 15, 2024
Billing assignment for shared Capacity Reservations	You can now assign the billing of any available capacity of a shared Capacity Reservati on to a consumer account that belongs to the same AWS organization.	October 14, 2024
PTP hardware clock - additional Region support	The PTP hardware clock is now also available in US East (Ohio) and Asia Pacific (Malaysia).	September 23, 2024

EC2 Instance Connect supports IPv6	You can now use EC2 Instance Connect to connect to the public IPv6 address of your instance.	September 23, 2024
EC2 Instance Connect prefix lists	You can now select a managed prefix list for IPv4 or IPv6 addresses when creating rules in your security groups to allow SSH traffic from the EC2 Instance Connect service.	September 23, 2024
New capabilities to manage On-Demand Capacity Reservations	You can now split your Capacity Reservation, move capacity between Capacity Reservations, and modify the instance eligibility attribute of your Capacity Reservation.	August 14, 2024
Hibernation support for C6g, C6gn, C6gd, C7g, C7gd, M6g, M6gd, M7g, M7gd, R6g, and R6gd	Hibernate your newly-launched instances running on C6g, C6gn, C6gd, C7g, C7gd, M6g, M6gd, M7g, M7gd, R6g, and R6gd instance types.	July 30, 2024
Hibernation support for AMIs that support Graviton instance types	Hibernate your newly-launched instances that were launched from an Amazon Linux or Ubuntu AMI that supports Graviton instance types.	July 30, 2024
Additional instance types supported for Credential Guard	You can now enable Credential Guard for C7i, C7-flex, M7i, M7i-flex, R7i, R7i-flex, and T3 instances.	June 26, 2024

EC2 instance type finder – additional parameters	The EC2 instance type finder now provides additional parameters for you to specify more detailed requirements for your workload.	June 5, 2024
New managed policy for EC2 Fast Launch	Added the EC2FastLaunchFullAccess policy to perform API actions related to the EC2 Fast Launch feature from an instance.	May 14, 2024
AMI deregistration protection	You can turn on deregistration protection on an AMI to prevent accidental or malicious deletion.	April 23, 2024
PTP hardware clock – instance type support	The PTP hardware clock is now available on M7a, M7g, M7i, R7a, and R7i instance types.	April 22, 2024
Added Nitro performance considerations for enhanced networking	This page focuses on network considerations to help with performance tuning for your Nitro based Amazon EC2 instances.	April 4, 2024
New managed policy for VSS based EBS snapshots	Amazon EC2 VSS has a new IAM managed policy available that you can add to your instance profile role to ensure that your permissions stay up-to-date and follow best practices.	March 28, 2024

PTP hardware clock – US East (N. Virginia)	The PTP hardware clock is now available in the US East (N. Virginia) Region.	March 26, 2024
Set IMDSv2 as the account default	You can set all new EC2 instance launches in your account to use Instance Metadata Service Version 2 (IMDSv2) by default.	March 25, 2024
Tag new Linux AMIs created from a snapshot	When you create a Linux AMI from a snapshot, you can tag the new AMI.	March 7, 2024
Tag new AMIs and snapshots when copying	When you copy an AMI, you can tag the new AMI and the new snapshots with the same tags, or you can tag them with different tags.	March 7, 2024
Remove AWS Management Pack pages	The AWS Management Pack was primarily used with Windows Server 2012 and prior. Those legacy OS platform versions are no longer supported. To manage and troubleshoot your fleet of servers running on AWS and on-premises, see AWS Systems Manager Fleet Manager.	February 12, 2024

EC2 Instance Connect preinstalled on macOS AMIs	EC2 Instance Connect now comes preinstalled on macOS Sonoma 14.2.1 or later, macOS Ventura 13.6.3 or later, and macOS Monterey 12.7.2 or later AMIs.	January 26, 2024
EC2 Instance Connect support for CentOS, macOS, and RHEL	You can now install EC2 Instance Connect on supported CentOS, macOS, and RHEL AMIs.	December 6, 2023
Hibernation support for C7a, C7i, R7a, R7i, and R7iz	Hibernate your newly-launched instances running on C7a, C7i, R7a, R7i, and R7iz instance types.	December 1, 2023
Amazon Q EC2 instance type selector	Amazon Q EC2 instance type selector considers your use case, workload type, and CPU manufacturer preference, as well as how you prioritize price and performance. It then uses this data to provide guidance and suggestions for Amazon EC2 instance types that are best suited for your new workloads.	November 28, 2023

Console-to-Code	Console-to-Code can help you get started with your automation code. Console-to-Code records your console actions, and then uses generative AI to suggest code in your preferred infrastructure-as code format. You can use the code as a starting point, customizing it to make it production-ready for your specific use case.	November 26, 2023
Configurable idle connection tracking timeouts	Security group connections that remain idle can lead to connection tracking exhaustion and cause connections not to be tracked and packets to be dropped. You can now set the timeout in seconds for security group connection tracking on an Elastic network interface.	November 17, 2023
PTP hardware clock	Supported instances now have a Precision Time Protocol (PTP) hardware clock. The PTP hardware clock supports either NTP or a direct PTP connection.	November 16, 2023
Change instance type of instance enabled for hibernation	You can now change the instance type of an instance enabled for hibernation when it is in the `stopped` state.	November 16, 2023

Instance topology	You can use the DescribeInstanceTopology API to detect the location of your instances, and then use this information to optimize HPC and ML jobs by running them on instances that are physically closer to each other.	November 13, 2023
EC2 Fast Launch shared AMI support	You can now enable EC2 Fast Launch on an AMI that's shared with you. When you enable EC2 Fast Launch on a shared AMI, the pre-provisioned snapshots for faster launching are created in your account.	November 6, 2023
Capacity Blocks for ML	You can now reserve GPU instances on a future date to support your short duration machine learning (ML) workloads.	October 31, 2023
Spot Instance hibernation	You can now hibernate your Spot Instances using the same hibernation experience and instance families that are currently available for On-Demand Instances.	October 24, 2023
Default settings for block public access for AMIs	Block public access for AMIs is now enabled by default for all new accounts and for existing accounts with no public AMIs.	October 20, 2023

Amazon EC2 Global View	Amazon EC2 Global View supports additional resource types and customizable display options.	October 18, 2023
Hibernation support for Ubuntu 22.04.2 LTS (Jammy Jellyfish)	Hibernate your newly-launched instances that were launched from the Ubuntu 22.04.2 LTS (Jammy Jellyfish) AMI.	October 16, 2023
Disable an AMI	You can disable an AMI to prevent it from being used for instance launches.	October 12, 2023
Attached EBS status checks	You can use the attached EBS status checks to monitor if the Amazon EBS volumes attached to an instance are reachable.	October 11, 2023
Hibernation support for Red Hat Enterprise Linux 9	Hibernate your newly-launched instances that were launched from the Red Hat Enterprise Linux 9 AMI.	October 2, 2023
Hibernation support for Microsoft Windows Server 2022	Hibernate your newly-launched instances that were launched from the Microsoft Windows Server 2022 AMI.	October 2, 2023
Hibernation support for AL2023	Hibernate your newly-launched instances that were launched from the AL2023 AMI.	October 2, 2023

Initiate interruption of Spot Instances in a Spot Fleet	You can select a Spot Fleet in the Amazon EC2 console and initiate an interruption of Spot Instances in the fleet so that you can test how the applications on your Spot Instances handle being interrupted.	September 21, 2023
Block public access to AMIs	You can enable *block public access for AMIs* at the account level to block any attempts to make your AMIs public.	September 12, 2023
Hibernation support for M7i and M7i-flex	Hibernate your newly-lau nched instances running on M7i and M7i-flex instance types.	August 22, 2023
EC2-Classic has been deprecated	With EC2-Classic, EC2 instances ran in a single, flat network shared with other customers. Amazon VPC replaces EC2-Classic. With Amazon VPC, your instances run in a virtual private cloud (VPC) that's logically isolated to your AWS account.	August 8, 2023
Dedicated Hosts	You can allocate Dedicated Hosts on specific hardware assets on an Outpost.	June 20, 2023
EC2 Instance Connect Endpoint	You can now connect to an instance through SSH or RDP without requiring the instance to have a public IPv4 address.	June 13, 2023

IMDS Packet Analyzer	You can now use the IMDS Packet Analyzer to identify sources of IMDSv1 calls on your EC2 instances.	June 1, 2023
EC2 Serial Console bare metal instances	The EC2 serial console now supports connectivity to the serial port of selected bare metal instances.	April 11, 2023
Launch template quotas	You can now view your quotas for launch templates and launch template versions in the Service Quotas console and by using the Service Quotas CLI.	April 3, 2023
Capacity Reservation utilization notifications	AWS Health now sends notifications when capacity utilization for Capacity Reservations in your account drops below 20 percent.	April 3, 2023
Capacity Reservation groups	You can now add Capacity Reservations that are shared with you to Capacity Reservation groups that you own.	March 30, 2023
Modify instance metadata options	You can now use the Amazon EC2 console to modify instance metadata options.	March 20, 2023
In-place macOS operating system updates	You can now perform in-place Apple macOS operating system updates on M1 Mac instances.	March 14, 2023

UEFI preferred	You can now create a single AMI that supports both Unified Extensible Firmware Interface (UEFI) and Legacy BIOS boot modes.	March 3, 2023
Modify an AMI for IMDSv2	Modify your existing AMI so that instances launched from the AMI require IMDSv2 by default.	February 28, 2023
Windows Virtualization-based security - Credential Guard	You can enable Credential Guard, a Virtualization-based security (VBS) feature, on supported Amazon EC2 instances.	January 31, 2023
New managed policy for EC2 Instance Connect Endpoint	Added the `Ec2InstanceConnectEndpoint` policy, which is attached to the **AWSServiceRoleForEC2InstanceConnect** service-linked role, to allow Amazon EC2 to perform actions on your behalf when you create an EC2 Instance Connect Endpoint.	January 24, 2023
AMI alias in launch templates	You can specify an AWS Systems Manager parameter instead of the AMI ID in your launch templates to avoid having to update the templates every time the AMI ID changes.	January 19, 2023

Hibernation support for C6i, I3en, and M6i	Hibernate your newly-launched instances running on C6i, I3en, and M6i instance types.	December 19, 2022
Torn write prevention	Improve the performance of your I/O-intensive relational database workloads and reduce latency without negatively impacting data resiliency with torn write prevention, a block storage feature.	November 29, 2022
ENA Express	Increase throughput and minimize tail latency of network traffic between EC2 instances with ENA Express.	November 28, 2022
Copy AMI tags	When you copy an AMI, you can copy your user-defined AMI tags at the same time.	November 18, 2022
AMI size for store and restore	The size of an AMI (before compression) that can be stored and restored to and from an Amazon S3 bucket can now be up to 5,000 GB.	November 16, 2022

priceCapacityOptimized allocation strategy for Spot Instances	A Spot Fleet that uses the `priceCapacityOptimized` allocation strategy looks at both price and capacity to select the Spot Instances pools that are the least likely to be interrupted and have the lowest possible price.	November 10, 2022
price-capacity-optimized allocation strategy for Spot Instances	An EC2 Fleet that uses the `price-capacity-optimized` allocation strategy looks at both price and capacity to select the Spot Instances pools that are the least likely to be interrupted and have the lowest possible price.	November 10, 2022
Cancel having an AMI shared with your account	If an AMI has been shared with your AWS account and you no longer want it shared with your account, you can remove your account from the AMI's launch permissions.	November 4, 2022
Transfer Elastic IP addresses	You can now transfer Elastic IP addresses from one AWS account to another.	October 31, 2022
Replace root volume	You can replace the root Amazon EBS volume for a running instance using an AMI.	October 27, 2022

Automatically connect instance to database	Use the automatic connection feature to quickly connect one or more EC2 instances to an RDS database to allow traffic between them.	October 10, 2022
AMI quotas	Quotas now apply to creating and sharing AMIs.	October 10, 2022
Configure AMI for IMDSv2	Configure your AMI so that instances launched from the AMI require IMDSv2 by default.	October 3, 2022
Initiate Spot Instance interruption	You can select a Spot Instance in the Amazon EC2 console and initiate an interruption so that you can test how the applications on your Spot Instances handle being interrupted.	September 26, 2022
Verified AMI provider	In the Amazon EC2 console, public AMIs that are owned by Amazon or a verified Amazon partner are marked **Verified provider**.	July 22, 2022
Placement groups on AWS Outposts	Added a host spread strategy for placement groups on an Outpost.	June 30, 2022
Dedicated Hosts on AWS Outposts	You can allocate Dedicated Hosts on AWS Outposts.	May 31, 2022

Instance stop protection	To prevent your instance from being accidentally stopped, you can enable stop protectio n for the instance.	May 24, 2022
UEFI Secure Boot	UEFI Secure Boot builds on the long-standing secure boot process of Amazon EC2 and provides additional defense-i n-depth that helps customers secure software from threats that persist across reboots.	May 10, 2022
NitroTPM	Nitro Trusted Platform Module (NitroTPM) is a virtual device that is provided by the AWS Nitro System and conforms to the TPM 2.0 specification.	May 10, 2022
AMI state change events	Amazon EC2 now generates an event when an AMI changes state. You can use Amazon EventBridge to detect and react to these events.	May 9, 2022
Describe public keys	You can query the public key and creation date of an Amazon EC2 key pair.	April 28, 2022
Create key pairs	You can specify the key format (PEM or PPK) when creating a new key pair.	April 28, 2022

Mount Amazon FSx file systems at launch	You can mount a new or existing Amazon FSx for NetApp ONTAP or Amazon FSx for OpenZFS file system at launch using the new launch instance wizard.	April 12, 2022
New launch instance wizard	A new and improved launch experience in the Amazon EC2 console, providing a quicker and easier way to launch an EC2 instance.	April 5, 2022
Automatically deprecate public AMIs	By default, the deprecation date of all public AMIs is set to two years from the AMI creation date.	March 31, 2022
AMI last launched time	The `lastLaunchedTime` indicates when your AMI was last used to launch an instance.	February 28, 2022
ED25519 keys	ED25519 keys are now supported for EC2 Instance Connect and EC2 Serial Console.	January 20, 2022
Additional RHEL platforms for Capacity Reservations	Additional Red Hat Enterprise Linux platforms for On-Demand Capacity Reservations.	January 11, 2022
Configure Windows AMIs for faster launching	Configure Windows AMIs to launch instances up to 65% faster, using pre-provisioned snapshots.	January 10, 2022

Instance tags in instance metadata	You can access an instance's tags from the instance metadata.	January 6, 2022
Capacity Reservations in cluster placement groups	You can create Capacity Reservations in cluster placement groups.	January 6, 2022
Spot Fleet launch-before-terminate	Spot Fleet can terminate the Spot Instances that receive a rebalance notification after new replacement Spot Instances are launched.	November 4, 2021
EC2 Fleet launch-before-terminate	EC2 Fleet can terminate the Spot Instances that receive a rebalance notification after new replacement Spot Instances are launched.	November 4, 2021
Compare timestamps	You can determine the true time of an event by comparing the timestamp of your Amazon EC2 Linux instance with ClockBound.	November 2, 2021
Share AMIs with organizations and OUs	You can now share AMIs with the following AWS resources: organizations and organizational units (OUs).	October 29, 2021
Spot placement score	Get a recommendation for an AWS Region or Availability Zone based on your Spot capacity requirements.	October 27, 2021

Attribute-based instance type selection for Spot Fleet	Specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes.	October 27, 2021
Attribute-based instance type selection for EC2 Fleet	Specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes.	October 27, 2021
On-Demand Capacity Reservation Fleet	You can use a Capacity Reservation Fleet to launch a group, or fleet, of Capacity Reservations.	October 5, 2021
Hibernation support for Ubuntu 20.04 LTS - Focal	Hibernate your newly-launched instances that were launched from the Ubuntu 20.04 LTS - Focal AMI.	October 4, 2021
T3 instances on Dedicated Hosts	Support for T3 instances on Amazon EC2 Dedicated Host.	September 14, 2021
Hibernation support for RHEL, Fedora, and CentOS	Hibernate your newly-launched instances that were launched from RHEL, Fedora, and CentOS AMIs.	September 9, 2021
Amazon EC2 Global View	Amazon EC2 Global View enables you to view VPCs, subnets, instances, security groups, and volumes across multiple AWS Regions in a single console.	September 1, 2021

Hibernation support for C5d, M5d, and R5d	Hibernate your newly-launched instances running on C5d, M5d, and R5d instance types.	August 19, 2021
Amazon EC2 key pairs	Amazon EC2 now supports ED25519 keys on Linux and Mac instances.	August 17, 2021
Prefixes for network interfaces	You can assign a private IPv4 or IPv6 CIDR range, either automatically or manually, to your network interfaces.	July 22, 2021
Event windows	You can define custom, weekly-recurring event windows for scheduled events that reboot, stop, or terminate your Amazon EC2 instances.	July 15, 2021
Resource IDs and tagging support for security group rules	You can refer to security group rules by resource ID. You can also add tags to your security group rules.	July 7, 2021
Deprecate an AMI	You can now specify when an AMI is deprecated.	June 11, 2021
Windows per-second billing	Amazon EC2 charges for Windows- and SQL Server-based usage by the second, with a one-minute minimum charge.	June 10, 2021

Root volume replacement	You can now use root volume replacement tasks to replace the root EBS volume for running instances.	April 22, 2021
Store and restore an AMI using S3	Store EBS-backed AMIs in S3 and restore them from S3 to enable cross-partition copying of AMIs.	April 6, 2021
EC2 Serial Console	Troubleshoot boot and network connectivity issues by establishing a connection to the serial port of an instance.	March 30, 2021
Boot modes	Amazon EC2 now supports UEFI boot on selected AMD- and Intel-based EC2 instances.	March 22, 2021
Create a reverse DNS record	You can now set up reverse DNS lookup for your Elastic IP addresses.	February 3, 2021
Tag AMIs and snapshots on AMI creation	When you create an AMI, you can tag the AMI and the snapshots with the same tags, or you can tag them with different tags.	December 4, 2020
Use Amazon EventBridge to monitor Spot Fleet events	Create EventBridge rules that trigger programmatic actions in response to Spot Fleet state changes and errors.	November 20, 2020

Use Amazon EventBridge to monitor EC2 Fleet events	Create EventBridge rules that trigger programmatic actions in response to EC2 Fleet state changes and errors.	November 20, 2020
Delete instant fleets	Delete an EC2 Fleet of type `instant` and terminate all the instances in the fleet in a single API call.	November 18, 2020
Hibernation support for T3 and T3a	Hibernate your newly-launched instances running on T3 and T3a instance types.	November 17, 2020
Amazon EFS Quick Create	You can create and mount an Amazon EFS file system to an instance at launch using Amazon EFS Quick Create.	November 9, 2020
Capacity Reservations in Wavelength Zones	Capacity Reservations can now be created and used in Wavelength Zones.	November 4, 2020
Hibernation support for I3, M5ad, and R5ad	Hibernate your newly-launched instances running on I3, M5ad, and R5ad instance types.	October 21, 2020
Spot Instance vCPU limits	Spot Instance limits are now managed in terms of the number of vCPUs that your running Spot Instances are either using or will use pending the fulfillment of open requests.	October 1, 2020

Capacity Reservations in Local Zones	Capacity Reservations can now be created and used in Local Zones.	September 30, 2020
Hibernation support for M5a and R5a	Hibernate your newly-launched instances running on M5a and R5a instance types.	August 28, 2020
Instance metadata provides instance location and placement information	New instance metadata fields under the `placement` category: Region, placement group name, partition number, host ID, and Availability Zone ID.	August 24, 2020
Capacity Reservation groups	You can use AWS Resource Groups to create logical collections of Capacity Reservations, and then target instance launches into those groups.	July 29, 2020
EC2Launch v2	You can use EC2Launch v2 to perform tasks during instance startup, if an instance is stopped and later started, if an instance is restarted, and on demand. EC2Launch v2 supports all versions of Windows Server and replaces EC2Launch and EC2Config.	June 30, 2020
Bring your own IPv6 addresses	You can bring part or all of your IPv6 address range from your on-premises network to your AWS account.	May 21, 2020

Launch instances using a Systems Manager parameter	You can specify a AWS Systems Manager parameter instead of an AMI when you launch an instance.	May 5, 2020
Resource tagging	You can tag egress-only internet gateways, local gateways, local gateway route tables, local gateway virtual interfaces, local gateway virtual interface groups, local gateway route table VPC associations, and local gateway route table virtual interface group associations.	January 10, 2020
Connect to your instance using Session Manager	You can start a Session Manager session with an instance from the Amazon EC2 console.	December 18, 2019
Default credit specification at the account level	You can set the default credit specification per burstable performance instance family at the account level per AWS Region.	November 25, 2019
Instance type discovery	You can find an instance type that meets your needs.	November 22, 2019
Dedicated Hosts	You can now configure a Dedicated Host to support multiple instance types in an instance family.	November 21, 2019

Instance Metadata Service Version 2	You can use Instance Metadata Service Version 2, which is a session-oriented method for requesting instance metadata.	November 19, 2019
Hibernation support for On-Demand Windows instances	You can hibernate On-Demand Windows instances.	October 14, 2019
Queued purchases of Reserved Instances	You can queue the purchase of a Reserved Instance up to three years in advance.	October 4, 2019
Diagnostic interrupt	You can send a diagnostic interrupt to an unreachable or unresponsive instance to trigger a kernel panic.	August 14, 2019
Elastic Fabric Adapter	EFA now supports Open MPI 3.1.4 and Intel MPI 2019 Update 4.	July 26, 2019
EC2 Instance Connect	EC2 Instance Connect is a simple and secure way to connect to your instances usi ng Secure Shell (SSH).	June 27, 2019
Host recovery	Automatically restart your instances on a new host in the event of an unexpected har dware failure on a Dedicated Host.	June 5, 2019

VSS application-consistent snapshots	Take application-consistent snapshots of all Amazon EBS volumes attached to your Windows instances using AWS Systems Manager Run Command.	May 13, 2019
Windows to Linux Replatforming Assistant for Microsoft SQL Server Databases	Move existing Microsoft SQL Server workloads from a Windows to a Linux operating system. Updated link points to the Microsoft SQL Server on Amazon EC2 User Guide.	May 8, 2019
Windows Automated Upgrade	Perform automated upgrades of EC2 Windows instances using AWS Systems Manager.	May 6, 2019

For information about the instance type releases for Amazon EC2, see Document history in the *Amazon EC2 Instance Types Guide*.
